INTRODUCTION

The Programmed Data Processor (PDP-1) is a high speed, solid state digital computer designed to operate with many types of input-output devices with no internal machine changes. It is a single address, single instruction, stored program computer with powerful program features. Five-megacycle circuits, a magnetic core memory and fully parallel processing make possible a computation rate of 100,000 additions per second. The PDP-1 is unusually versatile. It is easy to install, operate and maintain. Conventional 110-volt power is used, neither air conditioning nor floor reinforcement is necessary, and preventive maintenance is provided for by built-in marginal checking circuits.

PDP-1 circuits are based on the designs of DEC's highly successful and reliable System Modules. Flip-flops and most switches use saturating transistors. Primary active elements are Micro-Alloy and Micro-Alloy-Diffused transistors.

The entire computer occupies only 17 square feet of floor space. It consists of four equipment frames, one of which is used as the operating station.

CENTRAL PROCESSOR

The Central Processor contains the control, arithmetic and memory addressing elements and the memory buffer register. The word length is 18 binary digits. Instructions are performed in multiples of the memory cycle time of five microseconds. Add, subtract, deposit, and load, for example, are two-cycle instructions requiring 10 microseconds. Multiplication by subroutine requires 325 microseconds on the average. An optional automatic multiply and divide package is available. In this case multiplication requires an average of 20 microseconds. Program features include: single address instructions, multiple step indirect addressing and logical arithmetic commands. Console features include: flip-flop indicators grouped for convenient octal reading, six program flags for automatic setting and computer sensing and six sense switches for manual setting and computer sensing.

MEMORY SYSTEM

The coincident-current, magnetic core memory of a standard PDP-1 holds 4096 words of 18 bits each. Memory capacity may be readily expanded, in increments of 4096 words, to a maximum of 65,536 words. The read-rewrite time of the memory is five microseconds, the basic computer rate. Driving currents are automatically adjusted to compensate for temperature variations between 50 and 110 degrees Fahrenheit. The core memory storage may be supplemented by up to 24 magnetic tape transports.

Programmed Data Processor (PDP-1)

PDP-1 System Block Diagram

Central Processor Logic Layout

INPUT-OUTPUT

PDP-1 is designed to operate a variety of buffered input-output devices. Standard equipment consists of a perforated tape reader with a read speed of 400 lines per second, an alphanumeric typewriter for on-line operation in both input and output, and a perforated tape punch (alphanumeric or binary) with a speed of 63 lines per second. Optional external equipment includes: compatible magnetic tape (75 inches per second, even or odd parity); 16-inch cathode ray tube for graphic or tabular displays; light pen input; line printer (600 lines per minute); punched cards (input at 200 and output at 100 cards per minute); and a real time clock. All in-out operations are performed through the In-Out Register or through High Speed Input-Output Channels.

Of particular interest is the ease with which new, and perhaps unusual, external equipment can be added to PDP-1. Space is provided for additional gates to, and buffers from, the In-Out Register. The in-out system is sufficiently simple so that little control circuitry is needed for additional devices. New input-output instructions can be implemented easily at the Input-Output Taper-pin Panel.

The PDP-1 is also available with the optional Sequence Break System. This is a 16-channel automatic interrupt feature which permits concurrent operation of several in-out devices. A one-channel Sequence Break System is included in the standard PDP-1.

PROGRAMMING PDP-1

The Central Processor of PDP-1 contains the Control Element, the Memory Buffer Register, the Arithmetic Element, and the Memory Addressing Element. The Control Element governs the complete operation of the computer including memory timing, instruction performance and the initiation of input-output commands. The Arithmetic Element, which includes the Accumulator and the In-Out Register, performs the arithmetic operations. The Memory Addressing Element, which includes the Program Counter and the Memory Address Register, performs address bookkeeping and modification.

The powerful programming features of PDP-1 include:

- Multiple step indirect addressing
- Boolean operations
- Twelve variations of arithmetic and logical shifting, operating on 18 or 36 bits
- Fifteen basic conditional skip instructions (expandable by combining to form the inclusive OR of the separate conditions)
- Three different subroutine calling instructions
- Micro-coded operate instructions
- Index and Index-Conditional instructions
- Execute instruction
- Load-immediate instructions

Six independent flip-flops, called "program flags," are available for use as program switches or special in-out synchronizers. Two special instructions, Multiply Step and Divide Step, are included in the Instruction List. Multiply and divide subroutines using these instructions operate in about 325 and 440 microseconds respectively.

NUMBER SYSTEM

The PDP-1 is a "fixed point" machine using binary arithmetic. Negative numbers are represented as the one's complement of the positive numbers. Bit 0 is the sign bit which is ZERO for positive numbers. Bits 1 to 17 are magnitude bits, with Bit 1 being the most significant and Bit 17 being the least significant. To avoid a frequent point of confusion in one's complement arithmetic, the representation of -0 is automatically changed to $+0$ in certain arithmetic operations.

The conversion of decimal numbers into the binary system for use by the machine is performed by subroutines. Similarly the output conversion of binary numbers into decimals is done by subroutine. Operations for floating point numbers are handled by interpretive programming.

INSTRUCTION FORMAT

The Bits 0 through 4 define the instruction code; thus there are 32 possible instruction codes, not all of which are used. The instructions may be divided into two classes:

- Memory reference instructions
- Augmented instructions

In the memory reference instructions, Bit 5 is the indirect address bit. The instruction memory address, Y, is in Bits 6 through 17. These digits are sufficient to address 4096 words of memory.

PDP-1 Instruction Format

The augmented instructions use Bits 5 through 17 to specify variations of the basic instruction. For example, in the shift instruction, Bit 5 specifies direction of shift, Bit 6 specifies the character of the shift (arithmetic or logical), Bits 7 and 8 enable the registers (01 = AC, 10 = IO, and 11 = both) and Bits 9 through 17 specify the number of steps.

INDIRECT ADDRESSING

A memory reference instruction which is to use an indirect address will have a ONE in Bit 5 of the instruction word. The original address, Y, of the instruction will not be used to locate the operand, jump location, etc., of the instruction, as is the normal case. Instead, it is used to locate a memory register whose contents in Bits 6 through 17 will be used as the address of the original instruction. Thus, Y is not the location of the operand but the location of the location of the operand. If the memory register containing the indirect address also has a ONE in Bit 5, the indirect addressing procedure is repeated and a third address is located. There is no limit to the number of times this process can be repeated.

PDP-1 Logic Organization

OPERATING SPEEDS

Operating times of PDP-1 instructions are multiples of the memory cycle of 5 microseconds. Two-cycle instructions refer twice to memory and thus require 10 microseconds for completion. Examples of this are add, subtract, deposit, load, etc. The jump, augmented and combined augmented instructions need only one call on memory and are performed in 5 microseconds.

In-Out Transfer instructions that do not include the optional wait function require 5 microseconds. If the in-out device requires a wait time for completion, the operating time depends upon the device being used.

Each step of indirect addressing requires an additional 5 microseconds.

MANUAL CONTROLS

The Console of PDP-1 has controls and indicators for the use of the operator. All active registers have indicator lights on the Console. These indicators are primarily for use when the machine has stopped or when the machine is being operated one step at a time.

PDP-1 Control Panel

Three banks of toggle switches are available on the Console. These are the Address Switches (16 bits), the Test Word Switches (18 bits), and the Sense Switches (6 bits). The first two are primarily used in conjunction with the operating push buttons. The Sense Switches are present for manual intervention. The use of these switches is determined by the program.

CONSOLE PUSH BUTTONS

START

The computer will start. The first instruction comes from the memory location indicated by the address switches. If Start is pushed up, the computer enters the sequence break mode before starting; if pushed down, the computer leaves the sequence break mode. In either case, the overflow flip-flop is cleared.

STOP

The computer will come to a halt at the completion of the current memory cycle.

CONTINUE

The computer will resume operation starting at the state indicated by the lights.

EXAMINE

The contents of the memory register indicated by the Address Switches will be displayed in the Accumulator and the Memory Buffer lights.

DEPOSIT

The word selected by the Test Word Switches will be put in the memory location indicated by the Address Switches.

READ IN

The photoelectric punched tape reader will start operating in the Read-In mode.

CONSOLE TOGGLE SWITCHES

POWER

Turns all power to the computer on and off.

SINGLE STEP

When the Single Step Switch is on, the computer will halt at the completion of each memory cycle. This switch is particularly useful in debugging programs. Repeated operation of the Continue Push Button will step the program one cycle at a time. The programmer is thus able to examine the state of the machine at each step.

SINGLE INSTRUCTION

Same as Single Step except that entire instructions are stepped one at a time, regardless of the number of cycles required for their completion. (If Single Step and Single Instruction toggles are both on, the mode of operation will be single step.)

CONSOLE INDICATOR LIGHTS

○ RUN	On while the computer is executing instructions.
○ CYCLE	On after the completion of one or more instruction cycles with one or more to follow.
○ DEFER	On immediately prior to and during the execution of any deferred cycle.
○ H.S. CYCLE	On while the computer is executing a High Speed Channel Data Transfer.
○ BRK. CTR. 1	On while the computer is executing cycle 1 (deposit Accumulator) and cycle 3 (deposit Input-Output Register) of a sequence break.
○ BRK. CTR. 2	On while the computer is executing cycle 2 (deposit Program Counter) and cycle 3 of a sequence break.

PROGRAM FLAGS

On after the computer has executed the Set Selected Program Flag instruction or an in-out device has been activated, indicating its readiness to be serviced. (Can only be turned off or cleared by executing the Clear Selected Program Flag instruction.)

REGISTER INDICATOR LIGHTS

PROGRAM COUNTER

Displays 12 or 16 bits which represent the address of the next instruction to be executed.

INSTRUCTION	Displays 5 bits which represent the basic operation code of the instruction being executed.
MEMORY ADDRESS	Displays 12 or 16 bits which represent the address of the instruction being executed (after cycle 1) or the address of the operand (after succeeding cycles).
MEMORY BUFFER	Displays 18 bits which represent the instruction being executed (operation code and address part after cycle 1) or the 18-bit operand (after succeeding cycles).
ACCUMULATOR	Displays the 18 bits of the Accumulator which represent the results of arithmetic and logical operations.
IN-OUT	Displays the 18 bits of the Input-Output Register which represent information just transferred in or out of the computer or the results of certain arithmetic and logical operations

Standard PDP-1 Instruction List

This list includes the title of the instruction, the normal execution time of the instruction, (i.e., the time with no indirect address,) the mnemonic code of the instruction, and the operation code number. In the following list, the contents of a register are indicated by C (). Thus C (Y) means the contents of memory at Address Y; C (AC) means the contents of the Accumulator; C (IO) means the contents of the In-Out Register. An alphabetical and numerical listing of the instructions is contained on Pages 58 to 59.

MEMORY REFERENCE INSTRUCTIONS

ARITHMETIC INSTRUCTIONS

Add (10 μ sec)

add Y Operation Code 40

The new C (AC) are the sum of C (Y) and the original C (AC). The C (Y) are unchanged. The addition is performed with 1's complement arithmetic. If the sum of two like-signed numbers yields a result of the opposite sign, the overflow flip-flop will be set (see Skip Group instructions). A result of minus zero is changed to plus zero.

Subtract (10 μ sec)

sub Y Operation Code 42

The new C (AC) are the original C (AC) minus the C (Y). The C (Y) are unchanged. The subtraction is performed using 1's complement arithmetic. When two unlike-signed numbers are subtracted, the sign of the result must agree with the sign of the original Accumulator, or overflow flip-flop will be set (see Skip Group instructions). A result of minus zero is changed to plus zero, with the exception that $(-0) - (+0) = (-0)$.

Multiply Step (10 μ sec)

mul Y Operation Code 54

If Bit 17 of the In-Out Register is a ONE, the C (Y) are added to C (AC).

If IO Bit 17 is a ZERO, the addition does not take place. In either case, the C (AC) and C (IO) are rotated right one place. AC Bit 0 is made ZERO by this rotate. This instruction is used in the multiply subroutine.

Divide Step (10 μ sec)

dis Y Operation Code 56

The Accumulator and the In-Out Register are rotated left one place. IO Bit 17 receives the complement of AC Bit 0. If IO Bit 17 is ONE, the C (Y) are subtracted from C (AC).

If IO Bit 17 is ZERO, $C (Y) + 1$ are added to C (AC). This instruction is used in the divide subroutine. A result of minus zero is changed to plus zero.

Index (10 μ sec)

idx Y Operation Code 44

The C (Y) are replaced by $C (Y) + 1$ which are left in the Accumulator. The previous C (AC) are lost. Overflow is not indicated. If the original C (Y) equals the integer -1 , the result after indexing is plus zero.

Index and Skip if Positive (10 μ sec)
isp Y Operation Code 46

The C (Y) are replaced by C (Y) + 1 which are left in the Accumulator. The previous C (AC) are lost. If, after the addition, the Accumulator is positive, the Program Counter is advanced one extra position and the next instruction in the sequence is skipped. Overflow is not indicated. If the original C (Y) equals the integer, -1, the result after indexing is plus zero and the skip takes place.

LOGICAL INSTRUCTIONS

Logical AND (10 μ sec)
and Y Operation Code 02

The bits of C (Y) operate on the corresponding bits of the Accumulator to form the logical AND. The result is left in the Accumulator. The C (Y) are unaffected by this instruction.

LOGICAL AND TABLE

AC Bit	Y Bit	Result
0	0	0
0	1	0
1	0	0
1	1	1

Exclusive OR (10 μ sec)
xor Y Operation Code 06

The bits of C (Y) operate on the corresponding bits of the Accumulator to form the exclusive OR. The result is left in the Accumulator. The C (Y) are unaffected by this order.

EXCLUSIVE OR TABLE

AC Bit	Y Bit	Result
0	0	0
0	1	1
1	0	1
1	1	0

Inclusive OR (10 μ sec)
ior Y Operation Code 04

The bits of C (Y) operate on the corresponding bits of the Accumulator to form the inclusive OR. The result is left in the Accumulator. The C (Y) are unaffected by this order.

INCLUSIVE OR TABLE

AC Bit	Y Bit	Result
0	0	0
0	1	1
1	0	1
1	1	1

GENERAL INSTRUCTIONS

Load Accumulator (10 μ sec)

lac Y Operation Code 20

The C (Y) are placed in the Accumulator. The C (Y) are unchanged. The original C (AC) are lost.

Deposit Accumulator (10 μ sec)

dac Y Operation Code 24

The C (AC) replace the C (Y) in the memory. The C (AC) are left unchanged by this instruction. The original C (Y) are lost.

Deposit Address Part (10 μ sec)

dap Y Operation Code 26

Bits 6 through 17 of the Accumulator replace the corresponding digits of memory register Y. C (AC) are unchanged as are the contents of Bits 0 through 5 of Y. The original contents of Bits 6 through 17 of Y are lost.

Deposit Instruction Part (10 μ sec)

dip Y Operation Code 30

Bits 0 through 5 of the Accumulator replace the corresponding digits of memory register Y. The Accumulator is unchanged as are Bits 6 through 17 of Y. The original contents of Bits 0 through 5 of Y are lost.

Load In-Out Register (10 μ sec)

lio Y Operation Code 22

The C (Y) are placed in the In-Out Register. C (Y) are unchanged. The original C (IO) are lost.

Deposit In-Out Register (10 μ sec)

dio Y Operation Code 32

The C (IO) replace the C (Y) in memory. The C (IO) are unaffected by this instruction. The original C (Y) are lost.

Deposit Zero in Memory (10 μ sec)

dzm Y Operation Code 34

Clears (sets equal to plus zero) the contents of register Y.

Execute (5 μ sec plus time of instruction executed)

xct Y Operation Code 10

The instruction located in register Y is executed. The Program Counter remains unchanged (unless a jump or skip were executed). If a skip instruction is executed (by xct y), the next instruction to be executed will be taken from the address of the xct y plus one or the address of the xct y plus two depending on the skip condition. Execute may be indirectly addressed, and the instruction being executed may use indirect addressing. An xct instruction may execute other xct commands.

Jump (5 μ sec)

jmp Y Operation Code 60

The Program Counter is reset to Address Y. The next instruction that will be executed will be taken from Memory Register Y. The original contents of the Program Counter are lost.

Jump and Save Program Counter (5 μ sec)

jsp Y Operation Code 62

The contents of the Program Counter are transferred to bits 6 through 17 of the AC, the state of the overflow flip-flop to bit zero of the AC, and zeroes fill bits 1 through

5 of the AC. When the transfer takes place, the Program Counter holds the address of the instruction following the jsp. The Program Counter is then reset to Address Y. The next instruction that will be executed will be taken from Memory Register Y. The original C (AC) are lost.

Call Subroutine (10 μ sec)

cal Y Operation Code 16

The address part of the instruction, Y, is ignored. The contents of the Accumulator are deposited in Memory Register 100. The contents of the Program Counter (holding the address of the instruction following the cal) are transferred to bits 6 through 17 of the AC, the state of the overflow flip-flop to bit zero of the AC, and zeroes fill bits 1 through 5 of the AC. The next instruction that will be executed is taken from Memory Register 101. The cal instruction requires that the indirect bit be ZERO. The instruction may be used as part of a master routine to call subroutines.

Jump and Deposit Accumulator (10 μ sec)

jda Y Operation Code 17

The contents of the Accumulator are deposited in Memory Register Y. The contents of the Program Counter (holding the address of the instruction following the jda) are transferred to bits 6 through 17 of the AC, the state of the overflow flip-flop to bit zero of the AC, and zeroes fill bits 1 through 5 of the AC. The next instruction that will be executed is taken from Memory Register Y + 1. The jda instruction requires that the indirect bit be a ONE, but indirect addressing does not occur. The instruction is equivalent to the instructions dac Y, followed by jsp Y + 1.

Skip if Accumulator and Y differ (10 μ sec)

sad Y Operation Code 50

The C (Y) are compared with the C (AC). If the two numbers are different, the Program Counter is indexed one extra position and the next instruction in the sequence is skipped. The C (AC) and the C (Y) are unaffected by this operation.

Skip if Accumulator and Y are the same (10 μ sec)

sas Y Operation Code 52

The C (Y) are compared with the C (AC). If the two numbers are identical, the Program Counter is indexed one extra position and the next instruction in the sequence is skipped. The C (AC) and C (Y) are unaffected by this operation.

AUGMENTED INSTRUCTIONS

Load Accumulator with N (5 μ sec)

law N Operation Code 70

The number in the memory address bits of the instruction word is placed in the Accumulator. If the indirect address bit is ONE, (-N) is put in the Accumulator.

Shift Group (5 μ sec)

sft Operation Code 66

This group of instructions will rotate or shift the Accumulator and/or the In-Out Register. When the two registers operate combined, the In-Out Register is considered to be an 18-bit magnitude extension of the right end of the Accumulator.

Rotate is a non-arithmetic cyclic shift. That is, the two ends of the register are logically tied together and information is rotated as though the register were a ring. Shift is an arithmetic operation and is, in effect, multiplication of the number in the register by $2^{\pm N}$, where N is the number of shifts; plus is left and minus is right.

As bits are shifted out from one end of a register they are replaced at the other end by ones if the number is negative and zeroes if the number is positive. The sign bit is not shifted.

The number of shift or rotate steps to be performed (N) is indicated by the number of ONE's in Bits 9 through 17 of the instruction word. Thus, Rotate Accumulator Right nine times is 671777. A shift or rotate of one place can be indicated nine different ways. The usual convention is to use the right end of the instruction word (rar 1 = 671001).

When operating the PDP-1 in the single-step or single-instruction mode, shift group instructions may appear to be operating incorrectly (i.e., judging from the indicator lights of the control console). This occurs because some shift group instructions overlap into the beginning of the next instruction.

Rotate Accumulator Right (5 μ sec)

rar N Operation Code 671

Rotates the bits of the Accumulator right N positions, where N is the number of ONE's in Bits 9-17 of the instruction word.

Rotate Accumulator Left (5 μ sec)

ral N Operation Code 661

Rotates the bits of the Accumulator left N positions, where N is the number of ONE's in Bits 9-17 of the instruction word.

Shift Accumulator Right (5 μ sec)

sar N Operation Code 675

Shifts the contents of the Accumulator Right N positions, where N is the number of ONE's in Bits 9-17 of the instruction word.

Shift Accumulator Left (5 μ sec)

sar N Operation Code 665

Shifts the contents of the Accumulator left N positions, where N is the number of ONE's in Bits 9-17 of the instruction word.

Rotate In-Out Register Right (5 μ sec)

rir N Operation Code 672

Rotates the bits of the In-Out Register right N positions, where N is the number of ONE's in Bits 9-17 of the instruction word.

Rotate In-Out Register Left (5 μ sec)

ril N Operation Code 662

Rotates the bits of the In-Out Register left N positions, where N is the number of ONE's in Bits 9-17 of the instruction word.

Shift In-Out Register Right (5 μ sec)

sir N Operation Code 676

Shifts the contents of the In-Out Register right N positions, where N is the number of ONE's in Bits 9-17 of the instruction word.

Shift In-Out Register Left (5 μ sec)

sil N Operation Code 666

Shifts the contents of the In-Out Register left N positions, where N is the number of ONE's in Bits 9-17 of the instruction word.

Rotate AC and IO Right (5 μ sec)

rcr N Operation Code 673

Rotates the bits of the combined registers right in a single ring N positions, where N is the number of ONE's in Bits 9-17 of the instruction word.

Rotate AC and IO Left (5 μ sec)

rcl N Operation Code 663

Rotates the bits of the combined registers left in a single ring N positions, where N is the number of ONE's in Bits 9-17 of the instruction word.

Shift AC and IO Right (5 μ sec)

scr N Operation Code 677

Shifts the contents of the combined registers right N positions, where N is the number of ONE's in Bits 9-17 of the instruction word.

Shift AC and IO Left (5 μ sec)

scl N Operation Code 667

Shifts the contents of the combined registers left N positions, where N is the number of ONE's in Bits 9-17 of the instruction word.

Skip Group (5 μ sec)

skp Operation Code 64

This group of instructions senses the state of various flip-flops and switches in the machine. The address portion of the instruction selects the particular function to be sensed. All members of this group have the same operation code. The instructions in the Skip Group may be combined to form the inclusive OR of the separate skips. Thus, if Address 3000 is selected, the skip would occur if the overflow flip-flop equals ZERO or if the In-Out Register is positive.

The combined instruction would still take 5 microseconds.

The intent of any skip instruction can be reversed by making Bit 5 (normally the Indirect Address Bit) equal to ONE. For example, the Skip on Zero Accumulator instruction, with Bit equal to one, becomes Do Not Skip on Zero Accumulator.

Skip on ZERO Accumulator (5 μ sec)

sza Address 0100

If the Accumulator is equal to plus ZERO (all bits are ZERO), the Program Counter is advanced one extra position and the next instruction in the sequence is skipped.

Skip on Plus Accumulator (5 μ sec)

spa Address 0200

If the sign bit of the Accumulator is ZERO, the Program Counter is advanced one extra position and the next instruction in the sequence is skipped.

Skip on Minus Accumulator (5 μ sec)

sma Address 0400

If the sign bit of the Accumulator is ONE, the Program Counter is advanced one extra position and the next instruction in the sequence is skipped.

Skip on ZERO Overflow (5 μ sec)

szo Address 1000

If the overflow flip-flop is a ZERO, the Program Counter is advanced one extra position and the next instruction in the sequence will be skipped. The overflow flip-flop is cleared by the instruction. This flip-flop is set only by an addition or subtraction that exceeds the capacity of the Accumulator. (See definition of add and subtract instructions). The overflow flip-flop is not cleared by arithmetic operations which do not cause an overflow. Thus, a whole series of arithmetic operations can be checked for correctness by a single szo. The overflow flip-flop is cleared by the "Start" Switch.

Skip on Plus In-Out Register (5 μ sec)

spi Address 2000

If the sign digit of the In-Out Register is ZERO, the Program Counter is indexed one extra position and the next instruction in sequence is skipped.

Skip on ZERO Switch (5 μ sec)

szs Addresses 0010, 0020, ... 0070

If the selected Sense Switch is ZERO, the Program Counter is advanced one extra position and the next instruction in the sequence will be skipped. Address 10 senses the position of Sense Switch 1, Address 20 Switch 2, etc. Address 70 senses all the switches. If 70 is selected all 6 switches must be ZERO to cause the skip.

Skip on ZERO Program Flag (5 μ sec)

szf Addresses 0001 to 0007

If the selected program flag is a ZERO, the Program Counter is advanced one extra position and the next instruction in the sequence will be skipped. Address 1 selects Program Flag 1, etc. Address 7 selects all program flags which must be ZERO to cause the skip.

Operate Group (5 μ sec)

opr Operation Code 76

This instruction group performs miscellaneous operations on various Central Processor Registers. The address portion of the instruction specifies the action to be performed.

The instructions in the Operate Group can be combined to give the union of the functions. The instruction opr 3200 will clear the AC, put TW to AC, and complement AC.

Clear In-Out Register (5 μ sec)

cli Address 4000

Clears (sets equal to plus zero) the In-Out Register.

Load Accumulator from Test Word (5 μ sec)

lat Address 2000

Forms the inclusive OR of the C (AC) and the contents of the Test Word. This instruction is usually combined with Address 0200 (Clear Accumulator), so that C (AC) will equal the contents of the Test Word Switches.

Load Accumulator with Program Counter (5 μ sec)

lap Address 0100

Forms the inclusive OR of the C (AC) and the contents of the Program Counter (which contains the address of the instruction following the lap) in AC bits 6 through 17. Also, the inclusive OR of AC bit zero and the state of the overflow flip-flop is formed in AC bit zero. This instruction is usually combined with address 0200 (clear accumulator) so that the C (AC) will equal the contents of the overflow flip-flop (in AC bit zero) and the contents of the Program Counter (in AC bits 6 through 17). AC bits 1 through 5 are filled with zeroes.

Complement Accumulator (5 μ sec)

cma Address 1000

Complements (changes all ones to zeroes and all zeroes to ones) the contents of the Accumulator.

Halt

hlt Address 0400

Stops the computer.

Clear Accumulator (5 μ sec)
cla Address 0200

Clears (sets equal to plus zero) the contents of the Accumulator.

Clear Selected Program Flag (5 μ sec)
clf Address 0001 to 0007

Clears the selected program flag. Address 01 clears Program Flag 1, 02 clears Program Flag 2, etc. Address 07 clears all program flags.

Set Selected Program Flag (5 μ sec)
stf Addresses 0011 to 0017

Sets the selected program flag. Address 11 sets Program Flag 1; 12 sets Program Flag 2, etc. Address 17 sets all program flags.

No Operation (5 μ sec)
nop Address 0000

The state of the computer is unaffected by this operation, and the Program Counter continues in sequence.

In-Out Transfer Group (5 μ sec without in-out wait)
iot Operation Code 72

The variations within this group of instructions perform all the in-out control and information transfer functions. If Bit 5 (normally the Indirect Address bit) is a ONE, the computer will enter a special waiting state until the completion pulse from the activated device has returned. When this device delivers its completion, the computer will resume operation of the instruction sequence.

The computer may be interrupted from the special waiting state to serve a sequence break request or a high speed channel request.

Most in-out operations require a known minimum time before completion. This time may be utilized for programming. The appropriate In-Out Transfer can be given with no in-out wait (Bit 5 a ZERO and Bit 6 a ONE). The instruction sequence then continues. This sequence must include an iot instruction 730000 which performs nothing but the in-out wait. The computer will then enter the special waiting state until the device returns the in-out restart pulse. If the device has already returned the completion pulse before the instruction 730000, the computer will proceed immediately.

Bit 6 determines whether a completion pulse will or will not be received from the in-out device. When it is different than Bit 5, a completion pulse will be received. When it is the same as Bit 5, a completion pulse will not be received.

In addition to the control function of Bits 5 and 6, Bits 7 through 11 are also used as control bits serving to extend greatly the power of the iot instructions. For example, Bits 12 through 17, which are used to designate a class of input or output devices such as typewriters, may be further defined by Bits 7 through 11 as referring to Typewriter 1, 2, 3, etc. In several of the optional in-out devices, in particular the magnetic tape, Bits 7 through 11 specify particular functions such as forward, backward etc. If a large number of specialized devices are to be attached, these bits may be used to further decode the in-out transfer instruction to perform totally distinct functions.

STANDARD AND OPTIONAL EQUIPMENT

Standard Equipment

PERFORATED TAPE READER

The Perforated Tape Reader of the PDP-1 is a photoelectric device capable of reading 400 lines per second. Three lines form the standard 18-bit word when reading binary punched eight-hole tape. Five, six and seven-hole tape may also be read.

Read Perforated Tape, Alphanumeric
rpa Address 0001

This instruction reads one line of tape (all eight Channels) and transfers the resulting 8-bit code to the Reader Buffer. If bits 5 and 6 of the rpa instruction are both zero (720001), the contents of the Reader Buffer must be transferred to the IO Register by executing a rrb instruction. When the Reader Buffer has information ready to be transferred to the IO Register, Status Register Bit 1 is set to one. If bits 5 and 6 are different (730001 or 724001) the 8-bit code read from tape is automatically transferred to the IO Register via the Reader Buffer and appears as follows:

IO BITS	10	11	12	13	14	15	16	17
TAPE CHANNELS	8	7	6	5	4	3	2	1

The remaining bits of the IO Register are set to zero.

The code of the off-line tape preparation typewriter (Friden FIO-DEC Recorder-Reproducer) contains an odd parity bit. This bit may be checked by the read-in program. The FIO-DEC Code can then be converted to the Concise (6-bit) Code used by PDP-1 merely by dropping the eighth bit (parity).

A list of characters and their FIO-DEC and Concise Codes can be found on pages 60 through 61.

High Speed Perforated Tape Reader

Read Perforated Tape, Binary rpb Address 0002

The instruction reads three lines of tape (six Channels per line) and assembles the resulting 18-bit word in the Reader Buffer. For a line to be recognized by this instruction Channel 8 must be punched (lines with Channel 8 not punched will be skipped over). Channel 7 is ignored. The instruction sub 5137, for example, appears on tape and is assembled by rpb as follows:

Channel	8	7	6	5	4	3	2	1
Line 1	X		X				X	
Line 2	X		X		X			X
Line 3	X			X	X	X	X	X

Reader Buffer 100 010 101 001 011 111

(Vertical dashed line indicates sprocket holes and the symbols "X" indicate holes punched in tape).

If bits 5 and 6 of the rpb instruction are both zero (720002), the contents of the Reader Buffer must be transferred to the IO Register by executing a rrb instruction. When the Reader Buffer has information ready to be transferred to the IO Register, Status Register Bit 1 is set to one. If bits 5 and 6 are different (730002 or 724002) the 18-bit word read from tape is automatically transferred to the IO Register via the Reader Buffer.

Read Reader Buffer rrb Address 0030

When the rpa or rpb instructions are given with bits 5 and 6 both zero (720001 or 720002) information read from tape fills the Reader Buffer, but is not automatically transferred to the IO Register. To accomplish the transfer, these instructions must be followed by a rrb instruction. In addition, the rrb instruction clears Status Register Bit 1.

Read-In Mode

This is a special mode activated by the "Read-In" switch on the console. It provides a means of entering programs which does not rely on programs already in memory. Pushing the "Read-In" switch starts the reader in the binary mode. The first group of three lines, and alternate succeeding groups of three lines, are interpreted as "Read-In" mode instructions. Even-numbered groups of three lines are data. The "Read-In" mode instructions must be either "deposit in-out" (dioY) or "jump" (jmp Y). If the instruction is dio Y, the next group of three binary lines will be stored in memory location Y and the reader continues moving. If the instruction is jmp Y, the "Read-In" mode is terminated, and the computer will commence operation at the address of the jump instruction.

PERFORATED TAPE PUNCH

The standard PDP-1 Perforated Tape Punch operates at a speed of 63 lines per second. It can operate in either the alphanumeric mode or the binary mode.

Punch Perforated Tape, Alphanumeric ppa Address 0005

For each In-Out Transfer instruction one line of tape is punched. In-Out Register Bit 17 conditions Hole 1. Bit 16 conditions Hole 2, etc. Bit 10 conditions Hole 8.

Perforated Tape Punch

Punch Perforated Tape, Binary ppb Address 0006

For each In-Out Transfer instruction one line of tape is punched. In-Out Register Bit 5 conditions Hole 1. Bit 4 conditions Hole 2, etc. Bit 0 conditions Hole 6. Hole 7 is left blank. Hole 8 is always punched in this mode.

ALPHANUMERIC ON-LINE TYPEWRITER

The typewriter will operate in the input mode or the output mode.

Type Out tyo Address 0003

For each In-Out Transfer instruction one character is typed. The character is specified by the right six bits of the In-Out Register.

Type In tyi Address 0004

This operation is completely asynchronous and is therefore handled differently than any of the preceding in-out operations.

When a typewriter key is struck, the code for the struck key is placed in the typewriter buffer, Program Flag 1 is set, and the type-in status bit is set to one. A program designed to accept typed-in data would periodically check Program Flag 1, and if found to be set, an In-Out Transfer Instruction with address 4 could be executed for the information to be transferred to the In-Out Register. This In-Out Transfer should not use the optional in-out wait. The information contained in the typewriter buffer is then transferred to the right six bits of the In-Out Register. The tyi instruction automatically clears the In-Out Register before transferring the information and also clears the type-in status bit.

Alphanumeric Typewriter Keyboard

SEQUENCE BREAK MODE

The purpose of the Sequence Break Mode (or program interrupt) is to allow concurrent operation of several in-out devices and the main program sequence. It also provides a means of indicating to the computer that an in-out device is ready to accept or furnish data.

Interrupt requests can be received from a maximum of 12 in-out devices. Each such request sets a unique status bit. If the channel is free, the main program sequence is interrupted after completion of the current memory cycle and the C (AC) are automatically stored in memory location zero, the C (PC) in location 1, and the C (IO) in location 2. The time required to accomplish this is 15 μ sec. The C (PC) as stored in location 1 includes the state of the overflow flip-flop in bit zero. The Program Counter is then reset to the address 0003 and the program begins operating in the new sequence. The program beginning at location 0003 is usually designed to inspect the status bits, through the use of the Check Status instruction, to determine which in-out device caused the interrupt. A jump to the appropriate in-out subroutine can then be executed. Each such subroutine is terminated by the following instructions:

```

lac      0000 (to restore the AC)
lio      0002 (to restore the IO)
jmp (indirect) 0001 (to resume the main program)

```

The last of these three instructions restores the overflow and PC flip-flops and frees the channel thus allowing the next interrupt request received by the system to be processed. Interrupt requests that occurred while the channel was busy set status bits, and cause interrupts when the channel next becomes free.

In the standard PDP-1 the reader, punch, and typewriter are attached to the One-Channel Sequence Break System and five status bits are defined (see Check Status Instruction). The number of status bits is expanded as required by optional in-out equipment.

Three instructions are directly associated with the One-Channel Sequence Break System on the standard PDP-1:

Enter Sequence Break Mode

esm Address 0055

This instruction turns on the Sequence Break System, allowing automatic interrupts to the main sequence to occur.

Leave Sequence Break Mode

lsm Address 0054

This instruction turns off the Sequence Break System, thus preventing interrupts to the main sequence. Should interrupt requests occur while the system is off, the status bits will, nevertheless, continue to be set.

Clear Sequence Break System

cbs Address 0056

This instruction clears certain control flip-flops in the Sequence Break System thus nullifying the effect of any interrupt requests just granted or about to be granted (i.e., just prior to the transfer of the C (AC) to location zero).

MISCELLANEOUS

Check Status

cks Address 0033

This instruction checks the status of various in-out devices and sets IO Bits 0 through 4 for subsequent program interrogation as follows:

IO Bit Positions	Status Register Definitions
0	Set to 1 when light-pulse strikes pen Set to 0 at the start of each dpy instruction
1	Set to 1 when Punched Tape Reader Buffer has information ready to be transferred to IO Register Set to 0 by the reader return pulse or by the rrb instruction
2	Set to 1 when typewriter is free to receive a tyo instruction Set to 0 at the start of each tyo instruction
3	Set to 1 when typewriter key is struck Set to 0 by completion of tyi instruction
4	Set to 1 when tape punch is free to receive a ppa or ppb instruction Set to 0 at the start of each ppa or ppb instruction

Optional Equipment

AUTOMATIC MULTIPLY AND DIVIDE (TYPE 10)

This option replaces the Multiply Step and Divide Step instructions with the following instructions:

Multiply (14 to 25 μ sec)
mul Y Operation Code 54

The product of C(AC) and C(Y) is formed in the AC and IO registers. The sign of the product is in the AC sign bit. IO Bit 17 also contains the sign of the product. The magnitude of the product is the 34-bit string from AC Bit 1 through IO Bit 16. The C(Y) are not affected by this instruction. If the entire product results in a minus zero it is changed to a plus zero.

Divide (30 to 40 μ sec, except on overflow, 12 μ sec)
div Y Operation Code 56

The dividend must be in the AC and IO registers in the form indicated in the instruction. Multiply. IO bit 17 is ignored. The divisor is the C(Y). At the completion of the instruction, the C(AC) are the quotient and the C(IO) are the remainder. The sign of the remainder (in IO bit zero) is the sign of the dividend. The instruction that follows a DIV will be skipped unless an overflow occurs. The C(Y) are not affected by this instruction. If the remainder or quotient result in minus zero, that value is changed to plus zero.

If the magnitude of the high order part of the dividend is equal to or greater than the magnitude of the divisor, an overflow is indicated. In this case, the following instruction is not skipped. The original C(AC) and C(IO) are restored. The overflow flip-flop is not affected.

MEMORY MODULE (TYPE 12)

Each Memory Module consists of 4096, 18-bit words. A maximum of sixteen such modules may be connected to the PDP-1 thus allowing for a maximum memory capacity of 65,536 words.

MEMORY EXTENSION CONTROL (TYPE 15)

This control allows for memory expansion beyond 4096 to a maximum of 65,536 18-bit words in increments of 4096-word modules. It provides a single-level, indirect address mode called "extend", in addition to the normal multiple-level, indirect address mode of the standard PDP-1. A toggle switch labelled "extend", which is on the control console, provides for initial selection of the extend or normal mode in conjunction with the use of the Start or Read-In Push Buttons. During the operation of a program, the extend or normal mode can be selected as required through the use of two instructions provided with this option:

Enter Extend Mode (5 μ sec)
eem 724074

This instruction places the computer in the single-level, indirect address mode called "extend". In this mode, all memory reference instructions that are indirectly addressed refer to the location of a word which is taken as a 16-bit effective address. This address is contained in bits 2 through 17 of the specified word. The Program Counter (PC) and the Memory Address Register (MA) both become 16-bit registers. When a jsp, jda, cal, or lap (with address 300) instruction is executed, the AC receives the state of the overflow flip-flop in bit zero, the state of the indirect address mode (extend = 1, normal = 0) in bit 1, and the contents of the extended Program Counter in bits 2 through 17. Instructions not indirectly addressed are executed as in the standard PDP-1, but refer to the 4096 words in the memory module designated by the program counter extension, PC bits 2 through 5. Only bits 6 through 17 of the extended Program Counter act as a counter. Therefore, unless a transfer of control is indicated, an instruction in location 7777 is followed by the instruction in location 0000 of the same memory module, as specified by PC bits 2 through 5. In the extend mode, the cal instruction uses memory locations 0100 and 0101 in memory module zero.

Leave Extend Mode (5 μ sec)
lem 720074

This instruction places the computer in the multiple-level, indirect address mode called "normal". In this mode, the PDP-1 operates as usual and all addressing refers to the 4096 words in the memory module designated by the program counter extension, PC bits 2 through 5. As in the extend mode, the instructions jsp, jda, cal, and lap (with address 300) supply the AC with the contents of the overflow, indirect address mode, and PC flip-flops. In the normal mode, the cal instruction uses memory locations 0100 and 0101 in the memory module designated by the program counter extension, PC bits 2 through 5.

High Speed Channel transfers performed with extended memory refer directly to any of 65,536 memory locations, regardless of the state of the indirect address mode (extend or normal).

Sequence break operations with extended memory use Memory Module zero, locations 00 through 03 (one-channel system) or 00 through 77 (sixteen-channel system) to store the C(AC), C(PC), and C(IO) and to jump to the new sequence. The C(PC) as stored in the second fixed location assigned to each channel includes the state of the overflow flip-flop in bit zero, the state of the indirect address mode (extend = 1, normal = 0) in bit 1, and the contents of the extended Program Counter in bits 2 through 17. At the beginning of a sequence break the overflow and indirect address mode flip-flops are automatically set to zero. The indirect jump that terminates a sequence break requires the Sequence Break System to be on, temporarily places the computer in the extend mode, then restores the overflow, indirect address mode, and PC flip-flops to their previous stages (i.e., just prior to the beginning of the sequence break).

HIGH SPEED CHANNEL CONTROL (TYPE 19)

This control is used in conjunction with the High Speed Data Channel (Type 23). A maximum of three such channels can be attached to the PDP-1 through this control. Automatic Magnetic Tape Control Type 52 includes the installation of a Type 19 control. A high speed channel is used to automatically transfer blocks of words between core memory and an in-out device. Each channel is automatically interrogated at the completion of each memory cycle on a priority basis. The priority is wired and fixed. The Sequence Break System has an over-all priority just below that of the lowest priority high speed channel. When wired to this channel, a device communicates directly with memory through the Memory Buffer Register, by passing the IO Register. After proper initiation, data transfers proceed without disturbing the main program. If the channel has a word for or needs a word from the memory, the current program sequence pauses for one memory cycle (5 μ sec) to serve that channel, then continues. The maximum rate of transfer is 200,000 (18-bit) words per second.

SEQUENCE BREAK SYSTEM (TYPE 20)

The purpose of the Sequence Break System (or program interrupt system) is to allow concurrent operation of several in-out devices and the main program sequence. This system has, nominally, sixteen automatic interrupt channels arranged in a priority chain. Four fixed and unique memory locations are assigned to each sequence break channel. Channel zero (highest priority) uses locations 0, 1, 2, and 3; channel one uses locations 4, 5, 6, and 7; etc. A break to a particular sequence can be initiated by the completion of an in-out device, the program or any external signal. If this sequence has priority, the C(AC) are automatically stored in the first of four assigned memory locations, the C(PC) in the second, and the C(IO) in the third. The time required to accomplish this is 15 microseconds (during which other interrupts cannot occur). The C(PC) as stored in the second location includes the state of the overflow flip-flop in bit zero. The Program Counter is reset to the address of the fourth fixed location and the program begins operating in the new sequence. This new sequence may be broken by a higher priority sequence. A typical program for handling an in-out sequence would contain several instructions, including the appropriate IOT instruction. These are followed by load AC and load IO from their fixed

Sequence Break Indicator Panel

locations and an indirect jump to the location of the previous C(PC). This last instruction also restores the previous state of the overflow flip-flop and terminates the sequence.

When the Type 20 Sequence Break System is installed in the PDP-1, the standard one-channel system is removed. The three instructions associated with the one-channel system are retained and four additional instructions are provided:

Deactivate Sequence Break Channel

dsc 72kn50

Turn off the channel specified by kn, where kn equals 00 for channel zero, 01 for channel one, etc., and 17 for channel fifteen.

Activate Sequence Break Channel

asc 72kn51

Turn on the channel specified by kn.

Initiate Sequence Break

isb 72kn52

Initiate a sequence break on the channel specified by kn regardless of whether the channel is on or off.

Clear All Channels

cac 720053

Turns off all sixteen channels.

HIGH SPEED DATA CHANNEL (TYPE 23)

A Data Channel is used to automatically buffer the transfer of blocks of data between the PDP-1 and an input-output device. After proper initialization, Data Channel transfers proceed concurrently with computation. A maximum of three such channels can be attached to the PDP-1 through one Type 19 High Speed Channel Control. The maximum rate of transfer is 200,000 18-bit words per second.

A Data Channel has five major registers:

DATA BUFFER

This is an 18-bit buffer which is filled from the Memory Buffer Register of the PDP-1 for outgoing data or filled from an input-output device for incoming data.

INITIAL LOCATION COUNTER

This 16-bit register contains the memory address of the data word currently being transferred and is increased by one each time a word-transfer is completed.

WORD COUNTER

This 16-bit register contains the complement of the number of words remaining to be transferred. A one is added to this counter for each word-transfer.

REGISTER A

This 2-bit static register is set by an iot instruction at the same time the Word Counter is set. Bit zero is used to determine whether the block transfer is incoming or outgoing.

REGISTER B

This 2-bit static register is set by an iot instruction at the same time the Initial Location Counter is set.

The unused bits of Registers A and B may be optionally used to specify initial conditions that will remain static throughout the block transfer.

For example, Register B might be used to select one of four input-output devices. The block transfer completion pulses may be optionally used for Sequence Break System interrupts.

Two instructions are added to the PDP-1 with the installation of this option:

Set Channel Word Counter

scw 72c057

This instruction transfers IO Register bits zero and one to Register A and bits 2 through 17 to the Word Counter. Bit zero of the IO Register corresponds to bit zero of Register A and specifies an incoming block transfer if equal to one. If equal to zero, the transfer is outgoing. Bits 2 through 17 of the IO Register are all magnitude bits representing a positive, octal number that indicates the number of words to be transferred. The C(IO) remain unchanged. Octal digit c of the scw instruction may be 1, 2, or 3 to select one of three Data Channels.

Set Channel Initial Location

sci 72c157

This instruction transfers IO Register bits zero and one to Register B and bits 2 through 17 to the Initial Location Counter. The C(IO) remain unchanged. In addition, the SCI instruction starts the Data Channel operating by causing the emission of either an "outgoing data ready pulse" or an "incoming Data Buffer ready pulse". Upon receipt of one of these pulses, an input-output device begins requesting or providing data words through the Data Buffer. Octal digit c of the sci instruction may be 1, 2, or 3 to select one of three Data Channels.

PRECISION CRT DISPLAY (TYPE 30)

This sixteen-inch cathode ray tube display is intended to be used as an on-line output device for the PDP-1. It is useful for high speed presentation of graphs, diagrams, drawings, and alphanumerical information. The unit is solid state, self-powered and completely buffered. It has magnetic focus and deflection.

Precision CRT Display with Light Pen

Display characteristics are as follows:

- Random point plotting
- Accuracy of points ± 3 per cent of raster size
- Raster size 9.25 by 9.25 inches
- 1024 by 1024 addressable locations
- Fixed origin at center of CRT
- Ones complement binary arithmetic
- Plots 20,000 points per second

Resolution is such that 512 points along each axis are discernible on the face of the tube.

One instruction is added to the PDP-1 with the installation of this display:

Display One Point On CRT

dpy Address 0007

This instruction clears the light pen status bit and displays one point using bits 0 through 9 of the AC to represent the (signed) X coordinate of the point and bits 0 through 9 of the IO as the (signed) Y coordinate.

Cathode Ray
Tube Display

LIGHT PEN (TYPE 32)

The Light Pen is designed to be used with the CRT Display Type 30. By "writing" on the face of the CRT, stored or displayed information can be expanded, deleted or modified. Specifically, each time a light-pulse strikes the pen, the Light Pen status bit is set to one (see definition of Check Status Instruction) and Program Flag 3 is set to one. At the time the status bit is set, the x-y coordinates of the point just "seen" by the pen are in bits 0 through 9 of the AC and bits 0 through 9 of the IO, respectively (if the Display Instruction was given with the optional in-out wait). A program designed to accept Light Pen input would periodically check the Light Pen status bit and when found to be set, would store the C (AC) and C (IO) thereby defining the point just "seen" by the pen.

ULTRA-PRECISION CRT DISPLAY (TYPE 31)

The operation of this high resolution, five-inch cathode ray tube display is similar to that of the Type 30. Its resolution, accuracy, and stability, however, are such that it is much more suitable for the accurate, photographic recording of data. The specifications differ as follows:

Raster size 3 by 3 inches

Accuracy of points $\pm 1/2$ percent of raster size

4096 by 4096 addressable locations

Resolution is such that 1024 points along each axis are discernible on the face of the tube.

One instruction is added to the PDP-1 with the installation of this display:

Display One Point on Ultra-Precision CRT

dpp Address: 0407

This instruction displays one point using bits 0 through 11 of the AC to represent the (signed) X coordinate of the point and bits 0 through 11 of the IO as the (signed) Y coordinate.

Ultra-Precision CRT

CARD PUNCH CONTROL (TYPE 40)

This control allows for on-line, buffered operation of standard card punching equipment. It contains a buffer which is filled from the IO register using a series of iot instructions for each card row to be punched.

CARD READER CONTROL (TYPE 41)

This control provides for on-line, buffered operation of standard card reading equipment. It allows the reader outputs to be directed to the IO register.

MAGNETIC TAPE TRANSPORT (TYPE 50)

This transport is compatible with IBM tape formats with a recording density of 200 7-bit characters per inch, an inter-record gap of $3/4$ inches, and an interfile gap of $3 1/2$ inches. The read-write speed of 75 inches per second provides for a 15,000 character per second transfer rate. Rewind speed is 225 inches per second. The method of recording is non-return to zero. Standard IBM reels with the "file-protect ring" feature are used. A maximum of 24 tape transports may be connected to the PDP-1.

PROGRAMMED MAGNETIC TAPE CONTROL (TYPE 51)

This control transfers information between the computer and the tape one character at a time. All transfer operations, including timing, formatting, error checking and assembly of characters into computer words are performed by stored programs. The Type 51 allows a choice of tape format, including the standard IBM format described under Tape Transport Type 50. A maximum of three Tape Transports Type 50 can be connected to the PDP-1 through the Type 51 Control.

Five instructions are added to the PDP-1 with the installation of this option.

Magnetic Tape Select Mode (5 μ sec)

msm 720073

Clears the Control Unit Command Buffer, deposits the 8 least significant bits of the Input-Output Register in the Command Buffer, and selects a mode of operation based on the definition of each of the 8 bits as follows:

IO Bit Positions	If Zero	If One
10	Do not operate	Operate
11	Do not rewind	Rewind
12	Forward	Reverse
13	Read	Write
14	Odd Parity	Even Parity
15	75 inches/sec.	Not used

Bit positions 16 and 17 represent a 2-bit number used to select one of three transports as follows:

00	No Transport
01	Transport 1
10	Transport 2
11	Transport 3

For convenience, let an 18-bit word be designated by 6 octal digits labelled $x_1, x_2, x_3, x_4, x_5, x_6$. The octal notation that would then correspond to the above bit definitions for mode of operation would be:

x_6 (Control)	= 0 or 1	Do Not Operate (i.e., stop selected transport if not already stopped)
	= 2	Operate (i.e., according to octal digits x_5 and x_4)
	= 3	Rewind
x_5 (Function)	= 0	Read Odd Parity Forward
	= 1	Read Even Parity Forward
	= 2	Write Odd Parity Forward
	= 3	Write Even Parity Forward
	= 4	Read Odd Parity Reverse
	= 5	Read Even Parity Reverse
	= 6	Write Odd Parity Reverse
	= 7	Write Even Parity Reverse
x_4 (Transport)	= 0	No Transport
	= 1	Select Transport 1 at 75 inches/sec.
	= 2	Select Transport 2 at 75 inches/sec.
	= 3	Select Transport 3 at 75 inches/sec.
	= 4	No Transport

Magnetic Tape Control
Block Diagram

= 5 Not Used
 = 6 Not Used
 = 7 Not Used

Rewind constitutes a special case wherein x_s must be 4, 5, 6, or 7 because reverse motion must be indicated.

Magnetic Tape Check Status (5 μ sec) mcs 720034

Set IO bits 0 through 5 for subsequent program interrogation as follows:

IO Bit Positions	If One	If Zero
0	Not-Ready	Ready
1	Not-Rewinding	Rewinding
2	Not-In-File-Protect	In File-Protect (ring out of reel)
3	Not at Load Point	At Load Point (approx. 10 feet from physical end of tape)
4	Not Full Tape Supply	Full Tape Supply (approx. 100 feet of tape on take-up reel)
5	Not Low Tape Supply	Low Tape Supply (more than 100 feet of tape on take-up reel)
6	Not at End Point	At End Point (approx. 14 feet from trailing end of tape)
7	In Manual Mode	In Automatic Mode

In the above status-bit definitions, "ready" means that a tape transport:
 has been properly selected
 tape is not in motion
 is in "automatic"
 has its AC power on

Status may be checked for the transport currently in operation or the transport that was last selected, but currently not operating, by executing the mcs instruction alone. To check the status of any transport, execute a msm instruction using a code which selects the transport to be checked, but does not operate that transport, then the mcs instruction. Never, however, issue a msm instruction to the Control Unit if any transport is reading or writing.

Magnetic Tape Clear Buffer (5 μ sec) mcb 720070

Clears the Character Buffer and the Write Buffer. When writing IBM format, the end-of-record mark is written onto tape by executing a mcb instruction. Each of the 7 bits of the end-of-record mark represents the longitudinal parity of all the bits of the corresponding channel throughout the length of the record. The mcb instruction should immediately follow any msm instruction which calls for tape read or tape write.

If this is not done, the Character Buffer may never detect a character read from tape or an incorrect end-of-record mark may be written because the original state of the Write Buffer was unknown.

Magnetic Tape Write A Character (5 μ sec) mwc 720071

Each mwc instruction clears the Character Buffer, transfers the 6 most significant bits of the Input-Output Register to the Character Buffer (where the correct lateral parity bit is added) and writes the final, 7-bit character onto tape.

The mwc instruction that writes the first character on tape should be executed no sooner than 3 milliseconds after the msm instruction for operate-write (to account for tape start-time). Succeeding mwc instructions should occur every 65 microseconds (to write 200 characters per inch). After the last character of a record is written, 260 microseconds should elapse (e.g., by employing a time delay subroutine) and then the mcb instruction should be executed to mark the end-of-record. The time delay of 260 microseconds spaces tape such that 3 missing characters will be interpreted at this point when reading and hence, the read operation will recognize an end-of-record.

Magnetic Tape Read Character (5 μ sec) mrc 720072

Each mrc instruction transfers the contents of the Character Buffer (six data bits . . . the parity bit having been checked and dropped-out) to the 6 least significant bit positions of the Input-Output Register, clears the Character Buffer, and clears Program Flag 2.

It is generally desirable to program to read three characters from tape, assemble them in the Input-Output Register to form one computer word, and then deposit that word in a selected memory location. Since information transferred from the Character Buffer is combined with the contents of the Input-Output Register by an "inclusive or" operation, it is necessary that the Input-Output Register be cleared prior to assembling each group of three characters.

Program Flag 2 is automatically set by the Tape Control Unit when the first bit of a character read from tape enters the Character Buffer. Due to tape skew, all 7 bits of a character are not read simultaneously. Instead, at a tape speed of 75 inches per second, it may require as much as 25 microseconds for 7 bits to be read and entered into the Character Buffer. To read a character into the Input-Output Register it is necessary, therefore, to continually "look" at Program Flag 2 and immediately after finding it to be set, delay 25 microseconds and then execute the mrc instruction. This procedure assures the programmer that all 6 data bits were read and transferred to the Input-Output Register.

Due to the speed of tape and the density of the characters written on it, the mrc instruction must immediately be followed by the Program Flag 2 "look" procedure to find the next character on tape. This can, indeed, be done because the mrc instruction has made the necessary preparations by clearing the Character Buffer and Program Flag 2. Of necessity, therefore, the first 6 bits transferred to the Input-Output Register cannot be manipulated by the program until the next 6 bits begin entering the Character Buffer (as indicated by Program Flag 2).

At this point, the required 25 microsecond time period that accounts for tape skew can be used to manipulate the information in the Input-Output Register and to prepare to accept the next 6 bits of information from the Character Buffer.

The "look" for the first character of a record need not begin until approximately 3 milliseconds after the execution of the msm instruction for operate-read (to account for tape start-time). This time can be used by the programmer for any useful purpose.

The following Program Flags are used with the Basic Magnetic Tape Control Unit:

PROGRAM FLAG 2.

As previously described, this flag is automatically set when the first bit of a character read from tape enters the Character Buffer. It is used by the program to determine when a character is ready to be read into the IO Register.

PROGRAM FLAG 4.

This flag is automatically set if a parity error occurs while reading. To keep from disrupting the critical timing control provided by the program, it is generally desirable to read to the end-of-record before stopping the tape even though a parity error may have occurred within the record. Therefore, the state of Flag 4 is usually only checked at the end of a record. Corrective action usually involves backspacing one record and rereading the record. (Flag 4 is never set while writing on tape.)

Magnetic Tape Control and Transports

AUTOMATIC MAGNETIC TAPE CONTROL (TYPE 52)

This control automatically transfers information between the computer memory and the tape in variable-length blocks of characters. It allows computation to continue while the transfer is in process by using a High Speed Channel Control Type 19 in conjunction with a special-type data channel. Special features include scatter-read and gather-write, automatic bit-by-bit read-compare with core memory, automatic parity error detection while reading and writing, and rapid tape searching through its ability to skip a pre-selected number of blocks. Tape format is standard IBM as described under Magnetic Tape Transport Type 50.

A maximum of three Tape Control Units Type 52, each capable of handling as many as eight Tape Transports Type 50, can be connected to the PDP-1.

An Automatic Magnetic Tape Control (MTCU) has nine major registers:

DATA WORD BUFFER (DW)

This is an 18-bit buffer which is filled from the Memory Buffer Register of the PDP-1 when information is being written onto tape or filled from the Read Buffer of the Type 52 when information is being read from tape. Since it requires 200 microseconds to write the C(DW) onto tape or to fill the DW when reading tape, the MTCU automatically interrupts the PDP-1 once every 200 microseconds for a 5 microsecond data word transfer.

READ BUFFER (RB)

Each 7-bit character (6-bit code and parity bit) read from tape is momentarily stored in this 7-bit buffer. Here, a parity check is made, the parity bit is dropped, and the 6-bit character code is transferred to the DW. If a parity error is found, the Parity Error Bit, bit one of the State Register, is set. The first of three consecutive 6-bit character codes read from tape is stored in bits 0 through 5 of the DW, the second in bits 6 through 11, and the third in bits 12 through 17.

WRITE BUFFER (WB)

This 7-bit buffer obtains a 6-bit character code from the DW, supplies the correct parity bit, and transfers the resulting 7-bit character to the Write Head of the Tape Transport where it is written onto tape.

STATE REGISTER (SR)

This 18-bit register contains information concerning the status of the MTCU and the selected Tape Transport, including error conditions that may have occurred with the last tape record handled

by the MTCU. Under PDP-1 program control, the C(SR) can be transferred to the IO Register and there be interrogated.

FINAL ADDRESS REGISTER (FA)

This is a 16-bit register which is filled from the IO Register of the PDP-1 by a programmed instruction. It contains a core memory address equal to the address of the final data word to be handled plus one. The first four bits of this register designates one of sixteen 4096-word memory modules and the last twelve bits designates one of 4096 memory locations within that module. During read, write, compare, and space operations, this register is continually compared with the Current Address Register to determine if the operation has been completed.

CURRENT ADDRESS REGISTER (CA)

This is a 16-bit register which is filled from the IO Register of the PDP-1 by a programmed instruction. It contains the core memory address to or from which an 18-bit data word is currently being transferred. The first four bits of this register designates one of sixteen memory modules and the last twelve, one of 4096 memory locations within that module. The C(CA) is automatically increased by one after the completion of each data word transfer. During read, write, compare, and space operations, the C(CA) are continually compared with the C(FA) to determine if the operation has been completed. The C(CA) can be transferred to the IO Register by a programmed instruction.

COMMAND REGISTER (CR)

This 4-bit register is filled from the Memory Buffer Register of the PDP-1 with a code representing one of eleven tape functions such as read, write, rewind, etc. This code prepares the MTCU to carry-out the specified function.

TAPE UNIT REGISTER (TU)

This 3-bit register is filled from the Accumulator of the PDP-1 and is used to designate one of eight (0-7) Tape Transports attached to the specified MTCU.

STOP-CONTINUE REGISTER (SC)

This 2-bit register is filled from the Memory Buffer Register of the PDP-1 and is used to specify one of three end-of-record actions to be taken immediately after the tape operation has been completed.

Eight basic instructions are added to the PDP-1 with the installation of this option:

Magnetic Tape Unit and Final (5 μ sec) muf 72ue76

This instruction performs the following functions:

Bits 6 and 7 of the muf instruction are used to select one of three (0-2) Magnetic Tape Control Units (MTCU) attached to the PDP-1. Bits 15, 16, and 17 of the Accumulator replace the C(TU). These bits are used to select one of eight (0-7) Tape Transports (Units) attached to the specified MTCU. Bits 2 through 17 of the IO Register replace the C(FA). These bits represent a memory address equal to the final data word to be handled, plus one.

Bits 10 and 11 of the muf instruction replace the C(SC). These bits are used to select one of three "end-of-record actions":

- a) normal completion and stop,
- b) early completion and stop, or
- c) early completion and continue.

Bits 5, 8, and 9 of the muf instruction should be zero. If the selected MTCU is not busy, the muf instruction is properly executed and the next instruction in sequence is skipped. If busy, muf is performed as a nop instruction and the next instruction in sequence is executed. In either event, the C(IO) and C(AC) remain unchanged.

The "end-of-record actions" are defined as follows:

Normal Completion and Stop. After the end-of-record has been reached, the transport either writes an inter-record gap and stops or stops within an existing inter-record gap. After the 3 millisecond, transport stop-time has elapsed, the MTCU and PDP-1 are notified that the tape operation has been completed. Until such notification has been received, the MTCU is considered to be busy. Bit 3 of the State Register which can be examined by the computer program is a "one" if the MTCU is busy or a "zero" if the record has been completed.

Early Completion and Stop. This end-of-record action is identical to Normal Completion and Stop except that the completion notification is received by the MTCU 3 milliseconds earlier. Thus, the programmer can initiate a tape operation on a different Tape Transport attached to the same MTCU while the other Tape Transport is expending the 3 millisecond stop-time period. As before, completion is indicated by Bit 3 of the State Register being set to zero.

Early Completion and Continue. This end-of-record action is identical to Early Completion and Stop except that the Selected Transport continues in motion and continues to be under control of the selected MTCU. From the time Bit 3 of the State Register is set to zero (signifying "Record Complete") and up to 585 microseconds thereafter, new muf and mic instructions can be given. Thus, many records can be handled without stopping tape. If new instructions are not given during this time, "Early Completion and Stop" occurs after (a) two consecutive inter-record gaps (blank tape) have been written if the previous tape command was "write"; (b) the next record has been spaced-over (i.e., tape stops within the next available inter-record gap) if the previous tape command was "read".

Since any number of records can be "spaced" with a single tape command, early completion and continue is not normally specified with space commands unless the command is certainly intended to be changed during the

585 microsecond period. Failure to change a space command during this time results in tape-spacing until the end-of-reel is reached.

The octal digits, ue, within the muf instruction can be chosen from the following table to specify one of the allowable functions:

MUF UNIT-END (UE) TABLE

Function	Mnemonic	MTCU 0	MTCU 1	MTCU 2
Normal Completion and Stop	mnp	00	20	40
Early Completion and Stop	mep	01	21	41
Early Completion and Continue	mec	03	23	43

Magnetic Tape Initial and Command (5 μ sec)

mic 72uc75

This instruction performs the following functions:

Bits 6 and 7 of the mic instruction are used to select one of three (0-2) Magnetic Tape Control Units (MTCU) attached to the PDP-1.

Bits 2 through 17 of the IO Register replace the C(CA). These bits represent the initial address of a memory location whose contents is to be manipulated in a magnetic tape operation.

Bits 8 through 11 of the mic instruction replace the C(CR). These bits are used to select one of eleven tape functions as indicated in the MIC UNIT-COMMAND (UC) TABLE given below.

The C(SR) are cleared.

The selected tape transport is set into motion and begins to execute the specified tape function.

Bit 5 of the mic instruction should be zero. If the selected MTCU is not busy, the mic instruction is properly executed and the next instruction in sequence is skipped. If busy, mic is performed as a nop instruction and the next instruction in sequence is executed. In either event, the C(IO) remain unchanged.

The octal digits, uc, within the mic instruction can be chosen from the following table to specify one of the allowable tape commands:

Function	Mnemonic	MTCU 0	MTCU 1	MTCU 2
Stop	mst	00	20	40
Rewind	mrw	01	21	41
Backspace	mbs	03	23	43
Forward Space Check Even Parity	mfe	10	30	50
Forward Space Check Odd Parity	mfo	11	31	51
Write Even Parity	mwe	12	32	52
Write Odd Parity	mwo	13	33	53
Read and Compare Even Parity	mce	14	34	54
Read and Compare Odd Parity	mco	15	35	55
Read Even Parity	mre	16	36	56
Read Odd Parity	mro	17	37	57

STOP

The Stop Command should only be used when the previous muf instruction has called for Early Completion and Continue. The effect of a Stop Command is the same as that described for Normal Completion and Stop.

SPACE

For Backspace and Forward Space Commands the number of records to be spaced (or skipped-over) is equal to $C(FA) - C(CA) + 1$. To space 5 records, for example, set $C(FA) = 4$ and $C(CA) = 0$. In addition to spacing, the Forward Space Commands check for missing characters and for even or odd parity. Errors, if any, are indicated by the C(SR).

WRITE

With one exception, the first word of a record is written onto tape 5 milliseconds after the tape is set into motion. When starting a write operation at the Load Point, an 81 millisecond delay is used such that the first record on tape begins 6 inches from the Load Point Marker. The remainder of each record is written at the rate of one word every 200 microseconds. Writing continues until the $C(CA) = C(FA)$.

When the $C(CA) = C(FA)$ condition occurs:

- bit 7 of the State Register is set to one (signifying "Addresses Equal"),
- a sequence break occurs if the Sequence Break System is on,
- information transfers cease, but tape motion continues, and
- the address of the last word taken from memory is equal to the $C(FA)-1$.

If mrf and mri instructions (defined below) are executed within 100 microseconds after the $C(CA) = C(FA)$ condition occurs, the writing operation continues. This process is called "gather write". That is, information contained in scattered areas of memory can be "gathered" and written onto tape as a single, continuous record.

If the $C(CA) = C(FA)$ condition continues to exist for more than 100 microseconds, a longitudinal check character, defining the end-of-record, is automatically written. (Each of the 7 bits of the longitudinal check character represents the even parity of all the bits of the corresponding channel throughout the length of the record).

If a Write Command is executed with $C(CA) = C(FA)$ initially, then one inter-record gap is written and one of the "end-of-record actions" is taken. Controlled lengths of blank tape can be written in this manner by using "Early Completion and Continue".

Each character written onto tape is read and checked 4 milliseconds after it is written. If a parity error or missing character error occurs, it is indicated by the C(SR).

The memory contents of the PDP-1 are unchanged by magnetic tape write operations.

A character written onto tape that is comprised of seven, zero-bits is defined as an illegal character. Using PDP-1 Concise Code, such a "zero character" can be generated by writing a "space" or "tape-feed" character with even parity.

READ

The first word of a record is read from tape 9 milliseconds after the tape is set into motion. The remainder of each record is read at the rate of one word every 200 microseconds. Reading continues until the $C(CA) = C(FA)$ or the end-of-record is found.

When the $C(CA) = C(FA)$ condition occurs:

- bit 7 of the State Register is set to one (signifying "Addresses Equal"),
- a sequence break occurs if the Sequence Break System is on,
- information transfers cease, but tape motion continues, and the address of the last word stored in memory is equal to the $C(CA)-1$.

If mrf and mri instructions (defined below) are executed within 100 microseconds after the C(CA) = C(FA) condition occurs, the reading operation continues. This process is called "scatter read". That is, information read from a single, continuous record can be stored in scattered areas of memory.

If the C(CA) = C(FA) condition continues to exist for more than 100 microseconds, tape movement continues until the end-of-record is found. Information transfers do not occur during this time.

When the end-of-record is found:

- bit 3 of the State Register is set to zero (signifying "Record Complete"),
- a sequence break occurs if the Sequence Break System is on,
- the selected "end-of-record action" is taken, and
- the address of the last word stored in memory is equal to the C(CA)-1.

If a parity error or missing character error is detected while reading a record, it is indicated by the C(SR). The read operation, however, is in no way affected.

READ AND COMPARE

The first word of a record is read from tape 9 milliseconds after the tape is set into motion. This word fills the Data Word Buffer, but is not transferred to the computer. At the same time, the contents of the memory location specified by the Current Address Register is transferred to the selected MTCU. The two 18-bit words are then compared, bit by bit. The remainder of each record is read and compared with memory at the rate of one word every 200 microseconds. The read and compare operation continues until the C(CA) = C(FA), the end of record is found, or a read-compare error occurs.

When the C(CA) = C(FA) condition occurs:

- bit 7 of the State Register is set to one (signifying "Addresses Equal"),
- a sequence break occurs if the Sequence Break System is on,
- the read-compare operation ceases, but tape motion continues, and
- the address of the last word taken from memory for comparison is equal to the C(CA)-1.

If mrf and mri instructions (defined below) are executed within 100 microseconds after the C(CA) = C(FA) condition occurs, the read-compare operation continues. This process is called "gather-read-compare". That is, information contained in scattered areas of memory can be "gathered" and compared with information being read from a single, continuous record.

If the C(CA) = C(FA) condition continues to exist for more than 100 microseconds, tape movement continues until the end-of-record is found. Information is not read and compared during this time.

When the end-of-record is found:

- bit 3 of the State Register is set to zero (signifying "Record Complete"),
- a sequence break occurs if the Sequence Break System is on,
- the selected "end-of-record action" is taken, and
- the address of the last word taken from memory for comparison is equal to the C(CA)-1.

When a read-compare error occurs:

- bit 4 of the State Register is set to one (signifying "Read-Compare Error"),
- the read-compare operation ceases, but tape movement continues until the end-of-record is found, and
- the address of the last word taken from memory and successfully compared is equal to the C(CA)-1.

The memory contents of the PDP-1 are unchanged by magnetic tape read-compare operations.

Magnetic Tape Reset Final (5 μ sec) mrf 72u067

This instruction performs the following functions:

Bits 6 and 7 of the mrf instruction are used to select one of three (0-2) Magnetic Tape Control Units (MTCU) attached to the PDP-1.

Bits 2 through 17 of the IO Register replace the C(FA). These bits represent a memory address of the final data word to be handled, plus

The Tape Transport and the "end-of-record action" selected by the last-executed muf instruction remain selected.

Bit 5 and bits 8 through 11 of the mrf instruction should be zero.

The instruction following the mrf instruction is always executed. The C(IO) remain unchanged.

The mrf instruction is used for gather write, scatter-read, and gather-read-compare operations. To be effective, it must be given within 100 microseconds after the C(CA) = C(FA) condition occurs. If used in a sequence with the mri instruction as is the usual case, both the mrf and mri must be given within the 100 microsecond period.

The octal digit, u, within the mrf instruction can be 0, 2, or 4 to select MTCU 0, 1, or 2, respectively.

Magnetic Tape Reset Initial (5 μ sec) mri 72ug66

This instruction performs the following functions:

Bits 6 and 7 of the mri instruction are used to select one of three (0-2) Magnetic Tape Control Units (MTCU) attached to the PDP-1.

Bits 2 through 17 of the IO Register replace the C(CA). These bits represent the initial address of a memory location whose contents is to be manipulated in a magnetic tape operation.

Bit 10 of the mri instruction replaces bit 2 of the Command Register. This bit may be used to change the tape operation in process from read to read-compare or read-compare to read. It is also used to specify continuation of a write, read, or read-compare operation.

The Tape Transport and the "end-of-record action" selected by the last-executed muf instruction remain selected.

Bits 5, 8, 9, and 11 of the mri instruction should be zero.

The instruction following the mri instruction is always executed. The C(IO) remain unchanged.

The mri instruction is normally used in sequence with the mrf instruction to affect gather write, scatter read, and gather-read-compare operations. To be effective, both instructions must be given within 100 microseconds after the C(CA) = C(FA) condition occurs.

The octal digits, ug, within the mri instruction can be chosen from the following table to specify one of the allowable tape command charges or continuations.

MRI UNIT-CHANGE (UG) TABLE

Function	Mnemonic	MTCU 0	MTCU 1	MTCU 2
Change Read-Compare to Read (Even or Odd Parity)	mgr	02	22	42
Continue to Write (Even or Odd Parity)	mcw	02	22	42
Continue to Read (Even or Odd Parity)	mcr	02	22	42
Change Read to Read-Compare (Even or Odd Parity)	mgc	00	20	40
Continue to Read-Compare (Even or Odd Parity)	mcc	00	20	40
Read to Read-Compare, Even	mrc	00	20	40
Read to Read-Compare, Odd	mrc	00	20	40
Continue to Read-Compare	mcc	00	20	40

Magnetic Tape Examine States (5 μ sec) mes 72u035

This instruction performs the following functions:

Bits 6 and 7 of the mes instruction are used to select one of three (0-2) Magnetic Tape Control Units (MTCU) attached to the PDP-1. The C(SR) replace the C(IO). The C(SR) remain changed.

Bit 5 and bits 8 through 11 of the mes instruction should be zero.

The status of the selected MTCU and Tape Transport (TT) can be determined by programmed interrogation of the 18 binary digits transferred to the IO Register:

IO Register	State of MTCU and Transport
Bit 0 = 1	One or more of the conditions marked * exist
*Bit 1 = 1	Parity error
*Bit 2 = 1	Missing character error
*Bit 3 = 1	MTCU busy; if zero then Record Complete
*Bit 4 = 1	Read-compare error
*Bit 5 = 1	Illegal tape command
*Bit 6 = 1	High speed channel request late
Bit 7 = 1	C(CA) = C(FA); Addresses Equal
Bit 8 = 1	Selected Tape Transport (TT) ready
Bit 10 = 1	Selected TT is rewinding
Bit 11 = 1	Selected TT is in "file-protect" (i.e., ring is out of reel)
Bit 12 = 1	Selected TT is at Load Point (i.e., approximately 10 feet from physical end of tape).
Bit 13 = 1	Selected TT has Full Tape Supply (i.e., approximately 100 feet of tape on take-up reel).
Bit 14 = 1	Selected TT has Low Tape Supply (i.e., approximately 100 feet of tape on supply reel).
*Bit 15 = 1	Selected TT is beyond End Point (i.e., approximately 14 feet from trailing-end of tape).
Bit 16 = 1	Early Completion and Stop has been selected.
Bit 17 = 1	Early Completion and Continue has been selected.

In the above status-bit definitions, "ready" (bit 8) means that a tape transport: has been properly selected
tape is not in motion
is in "automatic"
has its AC power on

To examine states during the processing of a record, execute two mes instructions and accept the results only if they are equal. This avoids making an erroneous transfer of the C(SR) should it be in a dynamic state.

The octal digit, u, within the mes instruction can be 0, 2, or 4 to select MTCU 0, 1, or 2, respectively.

Magnetic Tape Examine Location (5 μ sec) mel 72u036

This instruction performs the following functions:

Bits 6 and 7 of the mel instruction are used to select one of three (0-2) Magnetic Tape Control Units (MTCU) attached to the PDP-1.

The C(CA) replace bits 2 through 17 of the IO Register. IO bits zero and one are set to zero. The address of the last word read into or compared with memory is equal to the C(CA)-1.

Bits 5 and bits 8 through 11 of the mel instruction should be zero.

To examine the C(CA) during the processing of a record, execute two mel instructions and accept the results only if they are equal. This avoids making an erroneous transfer of the C(CA) should it be in a dynamic state.

The octal digit, u, within the mel instruction can be 0, 2, or 4 to select MTCU 0, 1, or 2, respectively.

MAINTENANCE INSTRUCTIONS

Two special instructions are available for maintenance and diagnostic operations. They by-pass all interlocks of the MTCU.

Initiate a High Speed Channel Request (5 μ sec) inr 72ur67

This instruction forces the selected MTCU to initiate a High Speed Channel request. The contents of the memory location specified by the Current Address Register are transferred to the Data Word Buffer.

The octal digits, ur, within the inr instruction can be 02, 22, or 42 to select MTCU 0, 1, or 2, respectively and to initiate the request.

Clear Command Register (5 μ sec) ccr 72s067

This instruction forces the C(CR) and the C(TU) of the selected MTCU to be set to zero and places the selected MTCU in a non-busy state. This, in turn, causes the selected Tape Transport to stop. It is the only way, under program control, to bring the tape to rest during the processing of a record. The ccr instruction is particularly useful for adjusting the start-stop characteristics of a transport.

The octal digit, u, within the ccr instruction can be 1, 3, or 5 to select MTCU 0, 1, or 2, respectively and to clear the Command Register.

LINE PRINTER AND CONTROL (TYPE 62)

This is an on-line printing station capable of operating at 600 lines per minute (120 columns per line with 64 characters per column).

The printer uses the same character set as the standard PDP-1 Computeriter and the FIO-DEC Flexowriter except that all alphabetic characters are only upper case type. The printer also uses the same 6-bit Concise Codes as the Computeriter except for upper case, special characters. Characters constructed by using the non-spacing keys of the Computeriter can be made on the printer by over-printing a line. The complete printer character set and corresponding codes is listed on page 62.

Basically, the Line Printer Control consists of the following:

LINE BUFFER (LB)

This buffer is capable of storing 120, 6-bit character codes (or, for the sake of subsequent discussion, 40 three-character groups). It is filled, three characters at-a-time, from the Input-Output Register (IO) of the PDP-1.

COLUMN FILLING COUNTER (CC)

This counter directs the C(IO) to be transferred to one of the 40, three-character elements of the Line Buffer. For each three-character group transferred, the counter is automatically increased by one. It is stepped in this manner from 0 through 39 at which time the Line Buffer is entirely filled and ready to be printed. The counter is automatically reset to zero at the initiation of a print or space operation. Although the counter can be stepped from 0 through 63 and back to 0, information transferred with settings of 40 through 63 is lost.

WHEEL POSITION COUNTER (WC)

The "print-wheel" is a cylinder with 120 columnar positions. Each such position has 64 raised characters around the circumference of the cylinder. In each position, the characters are physically arranged according to their Concise Code. That is, following the "index point" is the character whose Concise Code is 00 followed by the character whose code is 01, 02, 03, etc., to 77 (octal).

The Wheel Position Counter follows the rotating print-wheel in such a way that at any given moment it contains the 6-bit Concise Code representing the character in position to be printed. The contents of this counter are continuously compared with the codes in each of the 120, 6-bit buffer elements. In all columnar positions where they are found to be the same, the character is printed. From the initiation of a print instruction, one full line is printed by one revolution of the print-wheel.

High Speed Line Printer

Three basic instructions are added to the PDP-1 with the installation of this option:

Fill Line Buffer (5 μ sec)
flb 72 1045

During the execution of this instruction, the three, 6-bit character codes in the IO Register are transferred to one of the 40, three-character elements of the Line Buffer according to the Column Filling Counter. In reference to the line to be printed, the characters in both the IO Register and in the Line Buffer are arranged from left to right.

The action caused by this instruction is completed in 5 microseconds. Bits 5 and 6 of the instruction are therefore not used to control in-out synchronization. The C(IO) remain unchanged.

Print a Line (5 μ sec)
prl 72 0045

This instruction performs the following functions in the order given:

Sets the print status bit to zero to indicate that the printer is busy printing.

Sets the Column Filling Counter to zero to prepare the printer for the next series of flb instructions.

Prints the line of information currently in the Line Buffer.

Sets the print status bit to one to indicate that the printer is ready to accept the next prl instruction.

The time required to print the line of information is 84 milliseconds. Bits 5 and 6 of prl instruction can therefore, be used to control in-out synchronization. Any print instructions given during the 84-millisecond period are ignored by the printer and will cause a "hang-up" condition if Bit 5 of the instruction is a one.

The prl instruction does not space paper; thus, many new symbols can be created by over-printing a line.

Space Line Printer (5 μ sec)
slp 72 2f45

This instruction performs the following functions in the order given:

Sets the space status bit to zero to indicate that the printer is busy spacing.

Sets the Column Filling Counter to zero to prepare the printer for the next series of flb instructions.

Spaces paper according to octal digit "f" within the slp instruction:

If S=0, space one line (1/6 inch)

If S=7, space to top of next page.

Sets the space status bit to one to indicate that the printer is ready to accept the next slp instruction.

The time required to space one line is 16 milliseconds. Bits 5 and 6 of the slp instruction can, therefore, be used to control in-out synchronization. It is permissible to fill the Line Buffer during spacing operations.

Spacing is controlled by a loop of 8-channel, perforated tape located at the printer station. The channel to be sensed, for purposes of spacing, is selected by the octal digit "f" within the slp instruction. Space control, then, may be defined as follows:

Tape channel designation	8 7 6 5 4	3 2 1
"f" digit designation	0 1 2 3 4	5 6 7
Number of lines spaced	1 2 3 6 11	22 33 66

(Vertical dashed line indicates location of sprocket holes)

Paper is spaced until a hole in the selected channel is sensed.

The "number of lines spaced" as given above are specifically related to standard 11-inch long sheets of paper. Regardless of the sheet length, however, channel one always spaces to the top of the next page and channel 8, single-spaces. The number of lines to be spaced, as specified by channels 2 through 7, is variable. The above table indicates suggested values for 11-inch paper.

STANDARD DEC PROGRAM LIBRARY FOR PDP-1

The standard library is designed to provide the nucleus of a growing system of programs and subroutines for the PDP-1. It consists of two broad categories of programs: (1) General and (2) Maintenance, all of which operate with the Standard PDP-1.

GENERAL

MACRO ASSEMBLY PROGRAM.

MACRO is a two-pass assembly program which produces a self-loading, machine language version of a program written in MACRO Symbolic Language. Important features of MACRO include:

Complete macro-instruction facilities with automatic dummy-argument assignment at call-time.

Automatic "constant" and "variable" assignment. Only unique constants are stored.

Symbol assignment printout in alphabetical or numerical order (at programmer option).

Symbol table punchout acceptable by the DDT Program (see below) to allow symbolic debugging.

Informative error printouts.

Automatic repeated assembly of a specified symbolic statement.

Automatic block storage assignment.

Punched block-letter tape labelling.

The MACRO package includes: (1) the Internal Operations Manual with complete, symbolic program listing, (2) the Programming Manual and (3) the necessary symbolic and self-loading machine language tapes.

DDT (DEC DEBUGGING TAPE).

This program is a complete symbolic-octal debugging aid. Its operation is controlled from the typewriter. Its major features are:

Ability to read MACRO generated symbol table tapes to allow completely symbolic debugging.

Examination and modification of the contents of selected memory locations.
 Block-search according to specified bits within a specified word.
 Printout or punchout of specified areas of memory.
 Read and compare tape with memory and printout discrepancies.

EXPENSIVE TYPEWRITER.

Under typewriter control, this program is capable of editing symbolic tapes by reading a tape into its "buffer", accepting additions and corrections, and punching out the amended "buffer" contents. It can perform tape-to-tape, tape-to-typewriter, and typewriter-to-tape translations.

UTILITY PROGRAM GROUP.

This group contains the following programs and subroutines:

Multiply Subroutine for 18-bits.

Divide Subroutine for 18-bits.

RANDOM, a random number generation subroutine for 18-bits.

SINGLEDEC, a single precision floating point package for arithmetic using an 18-bit fraction and an 18-bit exponent.

COPY, a short punched-tape duplicator.

DO, a short "Debug In Octal" routine.

PUNCHDUMP, a punchout routine that saves all non-zero memory.

MAINTENANCE

A complete set of standard test tapes and their description and use is delivered with each PDP-1.

APPENDIX

Abbreviated Instruction List

BASIC INSTRUCTIONS

INSTRUCTION	CODE #	EXPLANATION	OPER. TIME (μsec)	PAGE REF.
add Y	40	Add C(Y) to C(AC)	10	15
and Y	02	Logical AND C(Y) with C(AC)	10	16
cal Y	16	Equals jda 100	10	18
dac Y	24	Deposit C(AC) in Y	10	17
dap Y	26	Deposit contents of address part of AC in Y	10	17
dio Y	32	Deposit C(IO) in Y	10	17
dip Y	30	Deposit contents of instruction part of AC in Y	10	17
dis Y	56	Divide step	10	15
dzm Y	34	Deposit zero in Y	10	17
idx Y	44	Index (add one) C(Y), leave in Y & AC	10	15
ior Y	04	Inclusive OR C(Y) with C(AC)	10	16
iot Y	72	In-out transfer, see below		22
isp Y	46	Index and skip if result is positive	10	16
jda Y	17	Equals dac Y and jsp Y+1	10	18
jmp Y	60	Take next instruction from Y	5	17
jsp Y	62	Jump to Y and save program counter in AC	5	17
lac Y	20	Load the AC with C(Y)	10	17
law N	70	Load the AC with the number N	5	18
law-N	71	Load the AC with the number -N	5	18
lio Y	22	Load IO with C(Y)	10	17
mus Y	54	Multiply step	10	15
opr	76	Operate, see below	5	21
sad Y	50	Skip next instruction if C(AC) ≠ C(Y)	10	18
sas Y	52	Skip next instruction if C(AC) = C(Y)	10	18
sft	66	Shift, see below	5	18
skp	64	Skip, see below	5	20
sub Y	42	Subtract C(Y) from C(AC)	10	15
xct Y	10	Execute instruction in Y	5 + extra	17
xor Y	06	Exclusive OR C(Y) with C(AC)	10	16
