1.0 ABSTRACT

This program is a functional test of the LA00 terminal. It can test up to 40 terminals at a time, interfaced through a DZ11-A/E asynchronous multiplexers. This program was designed to test all of the functional characteristics of the LA00 terminal in a DMT or PMT environment.

1.1 Functional Description

This program consists of a test selection and control section, a console terminal driver section, multi unit DZ11 driver section, and twenty two functional tests. The tests are of three types, printer function tests, manual intervention tests, and exercisers.

1.2 Intended Users

This program was designed to test every functional characteristic of the LA00 terminal, and as such will be used for design maturity testing. The operator will have the option of running the program in a non-intervention mode, thus allowing the program to be used in a PMT environment. The tests were not written to F.S. or FA&T requirements, and the use of this program in those areas is not recommended.

2.0 REQUIREMENTS

2.1 Equipment

This program will require a PDP-11 processor, with 16K of memory. For each eight terminals to be tested a DZ11-A,E is required along with one H317-E distribution pannel for each sixteen terminals under test. A hardware switch register is supported, but is not required. If program control is to be via console terminal then a terminal and interface at the standard address & vector are required.

2.2 Related programs.

This program will perform cursorary testing of the DZ11 interface, and should not be considered a valid test of anything other than the LA00 terminal. PDP-11 processor and memory diagnostic programs, along with DZ11 diagnostic programs should be run periodically to insure correct operation of the system.

Other LA00 Diagnostic programs:

CZLAIA-0 this program

CZLAJA-0 LA00 FA&T Program

CZLA??-0 LA00 FS Diagnostic

2.3 Terminal Configuration

This program requires that all terminals to be tested be set up for 300 baud, 1 stop bit, Odd parity, and XON-XOFF enabled. Enter setup mode and type an 8 to get a printout of the current switch settings. If not correct change the switches then verify again using the 8 key again. These switches are located on the PC board directly under the keyboard assy.

3.0 LOADING PROCEDURE AND INITIALIZATION

Load the LA00 diagnostic program tape following normal procedures. If a hardware switch register does not exist, the program will use the contents of location 000176 as the value of the switches. Therefore, be sure to load location 000176 with the switch value before starting the program when not using switches.

3.1 Starting addresses

There are two starting addresses for this program. Starting at location 000200 will put the testing under switch register control. Starting at location 000204 will put the program under console control.

3.2 Modifications to program.

There are a number of common data storage locations which may be modified by the operator to compensate for non standard configurations, and different CPU types.

For DZ11's not at the standard addresses or vectors the locations named dzaddr and dzvect can be changed accordingly prior to starting the program.

Location loopc contains a time constant and is initially set for a PDP-11/20 processor. This time constant is not critical, but large variations from those listed in the table will result in inefficient operation. It is better to have a longer time constant than one too short because the routines that use the timeout feature will abort the timeout when the required input is received. Those tests that require manual intervention will not function correctly if the timeout is too fast for operator response times.

This table is duplicated in the listing.

```
loopc: 000314 ;time constant for 11/20
          ;set to 202 for 11/03
          ;set to 251 for 11/10
          ;set to 554 for 11/40
          ;set to 755 for 11/45, 11/60
          ;set to 1237 for 11/45, 11/70
          ;set to 2127 for 11/45 bip, 11/55
```

3.3 Execution time

At 300 baud and excluding manual intervention tests this program should take approximately 13 min.

4.0 Control and test selection

There are two means of controlling the execution of this program: via the console switch register, or via the console terminal.

If the program is started at location 200 and no hardware switch register exists the program will use the contents of location 176 as the switches

4.1 Switch register control

The various switches and their functions are listed below. switches may be changed and set as desired except as noted in the specific switch descriptions. Refer to the detailed switch descriptions for further, more complete information.

Switch number	Description
15	1(up) = Halt on error 0(down) = Continue after error report
14	1(up) = Loop on test if error detected 0(down) = Continue testing
13	1(up) = Inhibit error reports 0(down) = Print error reports
12	1(up) = Run individual test 0(down) = Run tests in sequence
10	1(up) = Get test no. from sws 4 : 0 0(down) = Use default test #0
9	1(up) = pmt mode minimum manual intervention 0(down) = dmt mode intervention required
8	1(up) = Run 1 pass of test sequence then halt 0(down) = Keep running test or sequence
4-	Test number selection

4.1.1 Switch 15

Placing switch 15 down will cause the program to continue on errors during any of the i/o tests. With switch 15 up, the program will halt (at errhlt) on any error during the i/o tests with the location of the error in R0. pressing continue will cause the program to continue if switch 12 is down (loop on error). With switch 12 up, pressing continue will cause the program to loop on the failing test.

4.1.2 Switch 14

Placing switch 14 up will cause the program to "loop on test" if an error is detected in that test. Error reports will be typed unless inhibited (switch 13 up). Looping will occur automaticly, without operator intervention, and will continue until the error ceases to happen, or the switch is placed down or =0.

4.1.2 Switch 14
Placing switch 14 up will cause the program to "loop on test" if an error is detected in that test. Error reports will be typed unless inhibited (switch 13 up). Looping will occur automaticly, without operator intervention, and will continue until the error ceases to happen, or the switch is placed down or =0.

4.1.3 Switch 13

Placing switch 13 up will inhibit the printing of all error reports. Can be used in conjunction with switch 14 to loop in errors for troubleshooting.

4.1.4 Switch 12

Placing switch 12 up will cause the program to loop in the current, or selected test. If switch 8 is up the test will halt at the end of the test. Pressing continue will cause the test to be started over again. Placing switch 12 down will cause the next sequential test to be executed, unless the test is an intervention test and PMT mode is selected.

4.1.5 Switch 11

Not used.

4.1.6 Switch 10

Placing switch 10 up will cause the program to use the contents of switches 4 thru 0 as the test number. If switch 12 is up this is the test that will be run, if switch 12 is down the sequence of tests to be run will start with this test.

4.1.7 Switch 9

Putting switch 9 up at the start of testing will inhibit manual intervention tests, and use a fixed set of parameters as listed in the description of each test.

4.1.8 Switch 8

With switch 8 down the program will loop on the selected test or test sequence as selected by switch 12. Placing switch 8 up will cause the program to halt at the completion of the current test, or test sequence. Pressing continue will result in the program restarting the test or sequence depending on switch 12.

4.1.9 Switches 4 to 0

Switches 4 to 0 are used to select specific tests when under switch register control. Test numbers are always in octal, from 00 to 22.

4.2 Keyboard control

Switches on the console switch register will have no effect when under terminal control except for switch 13.

The program will print the following : ENTER MODE D OR P
: respond by typing either a 'D' for DMT mode, or a 'P' for PMT mode (no manual intervention).

The program will print READY on the console, then wait for commands from the keyboard.

The following commands will be recognized :

R to run a selected test.
S to sequence thru tests.
L to loop on error.
H to halt on error.
C to clear the H & L commands
W to set the 'width' control

The period (.) is a terminator used in conjunction with the R and S commands to specify a single pass. That is to stop after running a test, or to stop after running a sequence of tests.

To abort operations and return to the WAIT state at any time type a CTL-C. The program will respond with READY and wait for command input.

Enter one command per line, followed by a return. If conflicting commands are entered the last entry will be used.

To exit 'command mode' type an escape. The program will type READY and begin execution of the commands. Commands can be entered at any time, but new tests will not start until the escape character is recieved.

Examples of commands :

R12 run test 12
R23. run test 23 then halt
S. sequence all tests then halt
S27 sequence all tests starting with test 27
W100 set width to 100 (octal) columns
 (204=132 colm, 120=80 colm)

If a test is selected that is an operator intervention test, and PMT mode is selected the following will be typed: RUN
INTERVENTION TEST ? answer Y or N. If Y is typed the test will be run. If N is typed a new test number will be requested.

The R,S,H,L,W, and C may be either upper or lower case, but the test number must always be a 2 digit octal number. The command, test number, and terminator are echoed by the program, thus each character will be printed twice if the terminal is in half duplex. If an error is detected in the test selection (illegal test number or command character) a question mark is printed and the message will be repeated.

READY

5.0 test groups

5.1 Terminal tests

5.2 Intervention tests

The tests 17 thru 24 require manual intervention. these tests are not run in PMT mode (see description of sw 9 4.1.7, and console control startup 4.2).

5.3 Exercisors

Tests 15 and 16 are designed as exercisors, and can be run for extended periods to 'burn in' the units under test.

5.4 Test assignments

Tests listed as DMT will not be executed in PMT mode. See description of switch 9 4.1.7 .

Test22	DMT	Pitch setup test

6.0. Test description

6.1 Data paths test00

This test will print four lines of alternating *U U pattern. It is a confidence test of the internal data bus, and receiver logic.

Example :

```
*U*U*U*U*U*U*U*U...
U*U*U*U*U*U*U*U...
*U*U*U*U*U*U*U*U...
U*U*U*U*U*U*U*U...
```

estimated time at 300 baud 18 seconds.

6.2 All printable characters test01

This test will print each of the printable characters in groups of four, separated by two spaces. The groups will be printed in order, and the number of groups per line will be dependent on the 'width' set at the start of the diagnostic. (default 132 colm)

Example :

```
AAAA BBBB CCCC DDDD
EEEE FFFF GGGG HHHH
3333 4444 5555 6666
% % % % @ @ @ @ + + + + ? ? ? ?
```

estimated time at 300 baud 30 sec

6.3 Non printable characters test02

This test checks all non-printable characters. In this test all non-printable character codes are transmitted, followed by the words: 'NON-PRINTING CHARACTER TEST.THE NEXT LINE SHOULD BE BLANK.
If any characters appear on the next line an error exists.

The following codes are transmitted :

000	NUL	002	STX	006	ACK
020	DLE	021	DC1	022	DC2
023	DC3	024	DC4	025	NAK
026	SYN	027	ETB	030	CAN
031	EM	032	SUB	034	FS
035	GS	036	RS	037	US
177	DEL	021	DC1(XON)		

estimated time at 300 baud 5 seconds

6.4 Dot matrix test03

This test will print the five characters ZH*#S , then print four lines of data that will create black boxes by overprinting the same five characters as above. Ten boxes will appear on each of the four lines at different spacings. This test will amplify any weak or intermittent head wire problems. The boxes should appear an even dark black, with no dots missing or lite streaks.

estimated time at 300 baud 10 seconds

6.5 Horizontal pitch test04

This test will print five groups of lines at each of the horizontal pitch settings. Each group of lines will consist of first a line stating the current pitch settings, then a line of the characters A thru Z. This is done for horizontal pitch settings of 10 CPI, 12 CPI, 13.2 CPI, and 16.5 CPI. The setup for this test is down line loaded.

estimated time at 300 baud 30 seconds

6.6 Space-Backspace test05

A line of alternating slashes and spaces is printed across the page. The program will then backspace through the line and overprint the slashes with backslashes. Two lines are printed for each pass of the test. The pattern produced is a line of alternating X's and spaces. The two slashes should cross exactly in the middle creating the X character.

example : X

estimated time at 300 baud 45 seconds

6.7 Set margins test06

This test will set 4 pairs of left and right margins, then it will print a line of '='s that should be within those margins. Also a message will be sent specifying an error if it's not at the left margin. A reference line will be printed showing the margin limits being set up. All horizontal pitch settings will be tested.

example :

```
.....V.....V.....
=====
ERROR IF NOT AT LH MARGIN
```

estimated time at 300 baud 40 seconds

6.8 horizontal tabs test07

this test will print a reference line composed of a number of periods followed by a 'V'. This pattern is repeated across the page. The location of each V will mark the location of a tab stop set by the program. Three lines will then be printed under this reference line, composed of a horizontal tab followed by an I, repeated across the page. The I's should line up directly under the reference line V's.

Example :

```
.....V.....V.....V.....V....
      |      |      |      |
      |      |      |      |
      |      |      |      |
```

This will be repeated for a variety of different tab settings. The number of tabs per line will be controled by the 'width' specified at the start of the diagnostic.

estimated time at 300 baud, 132 col - 2 min

6.9 Multiple line feed test10

This test will print a reference line of dashes then skip N lines and print the no. of lines skipped along with some dashes for visual reference. Each skip count is done twice for N = 1 to 7. Vertical pitch will be 6 lines per inch.

EXAMPLE :

```
-----
-----01
-----01

-----02

-----02

-----03

-----03
```

estimated time at 300 baud 15 seconds

6.10 Horizontal motion test11

This test will exercise the head positioning logic by printing a line of H's at random column locations within the line. The head will be positioned using spaces, backspaces, and carriage returns followed by spaces. The number of columns printed is controlled by the 'width' as set at the start of the program. All H's should be evenly spaced, with no overprints.

estimated time at

300 baud 4 min

6.11 Buffer overrun test12

This test will force the terminal to send an XOFF char (023) by issuing a series of time consuming movement commands, followed by enough characters to fill the buffer past it's 118 character limit. When the terminal has emptied the buffer to the 10 character level it should transmit an XON character (021) allowing the host to finish sending data. Any terminal that fails to send the XON will be considered to be 'dead', and will be deselected or set inactive.

estimated time at 300 baud 10 seconds.

6.12 Vertical pitch test13

This test will print six lines at each of the vertical pitch settings: 2,3,4,6,8 and 12 lines per inch. The line printed will be a message that lists the current CPI and LPI settings. The setup for this test is down line loaded.

estimated time at 300 baud 40 seconds

6.13 Bell test14

This test checks the printer bell to insure that eight bells are distinctly heard, even when sent at the maximum transfer rate. The program sends 8 bell codes at the maximum rate to the printer then waits 2.5 seconds to allow the operator to hear the bells.

estimated time 1 second

6.14 LA00 Life test15

Ordinarily this test simply prints a line of 'A's.

When this test is looped on, it prints two lines of each printable character. When all printable characters have been done, they will simply be repeated. The current pass number is printed on each line, with a 1 column offset on each new line. The number of characters per line will be determined by the 'width' as selected at program startup.

example :

```
01 AAAAAAAAAAAAAAAAAAAAAAAAAA..  
A 01 AAAAAAAAAAAAAAAAAAAAAAAAAA..  
BB 01 BBBBBBBBBBBBBBBBBBBBBB..  
BBB 01 BBBBBBBBBBBBBBBBBBBBBB..  
CCCC 01 CCCCCCCCCCCCCCCCCCCC..  
CCCCC 01 CCCCCCCCCCCCCCCCCCCC..
```

estimated time 1 line 300 baud 5 seconds

6.15 LA00 dynamic exercisor test16

This test will print 35 lines of mixed format data. A pattern will be created which is comprised of the upper and lower case character set plus eight of the special symbols. This pattern will be in the form of a 10'' by 6'' matrix, where the upper left corner will have the greatest character density and the lower right corner will have the lowest density. All possible combinations of horizontal and vertical pitch will be used.

estimated time at 300 baud 2.5 min.

intervention tests

no time estimates given

6.16 interface baud rates test17

This test will request that the operator change the speed on all terminals to 110 baud. The program will then transmit a message to all terminals at this baud rate, identifying the current speed, then by use of the escape sequence ESC [Oc the terminal ID message will be sent from each terminal to the PDP-11 to verify correct transmission and reception by the terminal. This same procedure is repeated for 300 baud. because of intervention no time estimate is given

6.17 Keyboard echo test20

This test will require the operator to type all the printing keys on the keyboard. If any keys are not seen by the host they will be requested again, and a third time if necessary. Instructions will then be typed to press the tab, return, and other non printing keys. five seconds is allowed per key delay.

6.18 Character code echo test21

This test will print the octal code of any key pressed, along with the ascii character. Where the character is a non printable code the mnemonic of that code will be printed. The delete char will be echoed as a mnemonic, then the test will be done.

6.19 Pitch setup test22

this test will require the operator to change the terminal setup to that requested. After each setup change the PDP-11 will send a line of data that should conform to the params setup. The data sent after vertical pitch changes will be a number of short lines that should span 1 inch vertically. That is eight lines after the change to 8 LPI etc.

:.....:
: BUFFER OVERRUN TEST :
: THIS TEST WILL FORCE THE TERMINAL TO TRANSMIT AN XOFF :
: BY JAMMING A SERIES OF TIME CONSUMEING MOVEMENT CHARS :
: INTO THE BUFFER , FOLLOWED BY ENOUGH CHARS TO FILL :
: THE BUFFER. WHEN THE TERMINAL HAS EMPTIED THE BUFFER :
: TO 10 CHARS IT SHOULD SEND AN XON. :
:.....:

: : : : :
: LIFE TEST #5 : : : : :
: : : : :
: THIS TEST WILL PRINT A CONTINUOUS PATTERN :
: OF ALL PRINTABLE CHARACTERS. EACH CHARACTER :
: WILL BE PRINTED ON 2 FULL LINES, :
: WITH THE PASS COUNT INBEDDED IN THE LINES. :
: THIS PATTERN WILL PRECESS 1 CHAR POSITION :
: EACH LINE PRINTED. :
: LOOPING IS CONTROLLED BY SWITCH #12. :
: : : : :
